Trend in Truck Design as Revealed by 1921 Specifications

Thirty per cent increase in number of 2½ ton models. Marked tendency toward the four-speed gear box. Worm drive still predominates and shows a gain at expense of internal gear and chain drive. Disk clutch, vacuum fuel feed, pressed steel frame and block-cast cylinders gain in popularity.

By Herbert Chase

JUDGED by the number of models listed (and all figures given in this review refer to the number of models listed in tables compiled by CLASS JOURNAL publications) the most popular size of truck in 1921 is the 1½-ton, as was the case also in 1920. There has been an increase of about 14 per cent in the number of models of this size. The 2½-ton job is second in popularity, and the number of models of this size listed shows a 30 per cent increase. The 3½-ton is a close third in number of models, but the percentage gain in this size is only 17.

Among the outstanding tendencies revealed by the accompanying table and chart is that toward a more general use of the four-speed gearset. This tendency has been increasing rapidly since 1917-18, when it was given impetus by the design of war trucks which incorporated this feature and demonstrated its utility. Over 57 per cent of all models listed now have four-speed transmissions. The remaining models nearly all have three speeds, though there are a few which have two, five, or more than five gear changes.

Pneumatic tire equipment has become standard on trucks of one ton and less capacity and is increasing, at least as optional equipment on many larger sizes. The use of electric starting and lighting has increased slightly, its use being much more frequent on the light pneumatic tired trucks, but is not confined to this type.

The use of wood wheels still predominates, but the ratio of wood to metal is now less than 2 to 1, whereas last year it was over 3 to 1, indicating, of course, that the metal wheel is increasing in popularity.

Both the number and percentage of models using the worm gear final drive have increased at the expense of the internal gear and chain types. The bevel gear and double reduction types also show an increase, though the percentage of models using these types is not large.

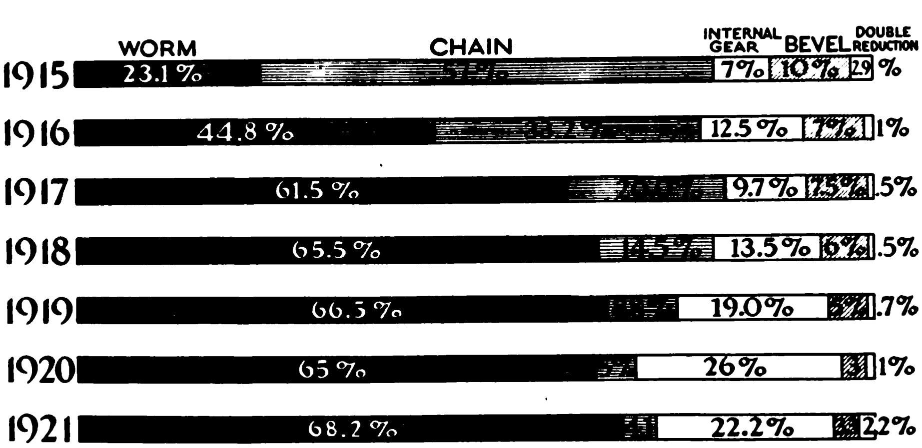
The number of models of trucks in which the gearset is mounted amidship is almost the same as the number in which a unit powerplant is employed. Some regard the latter type as less accessible than the former, but the use of unit construction cuts down the number of parts required, so that there appears to be little choice between the two types. The practice of making the gearset a unit with the rear axle has been entirely abandoned.

The cone clutch, which six years ago was used on more than 40 per cent of truck models, is now used by less than 6 per cent. The disk and plate types have become increasingly popular and are now used on over 94 per cent of the models listed, by far the majority of these using the multiple disk type. A large proportion of the latter run dry, fewer than formerly using the wet plate type.

Practice in respect to the engine type shows no very marked change. For many years past the four-cylinder engine has been used on over 95 per cent. of the models offered, and in 1921 it is employed in 99 per cent. There are still many advocates of pair-cast cylinders, over 28 per cent of the models listed using this type of construction, as against 69.7 per cent block-cast and 1.8 per cent separately cast. Block casting has shown a steady increase for many years, and the greater facility in machining and greater rigidity which this construction affords appears to be largely responsible for the increase.

Thermo-syphon cooling reached the height of its popularity in 1919 when it was employed on 24 per cent of the models. At present 16 per cent are using this system of cooling, while 84 per cent use pump circulation, which is more positive in action, while the higher water velocity enables the use of a smaller and lighter radiator.

Gravity fuel feed systems have declined in popularity since 1919, when 79 per cent of models used this system. It is still the most used, with 64 per cent of the installations, but the use of vacuum feed is rapidly increasing and is now applied to 34.5 per cent of the models listed. Gravity feed will no doubt continue in the majority as long as space for a gravity tank can be provided, for the vacuum and pressure systems (the latter of which has almost disappeared) involves the use of elements which are not otherwise required.



Trend of design with respect to final drive

(Continued on page 348)

ABBREVIATIONS—Types of Construction

- *—other options
- **amid**—amidships
- **auto**—automatic
- **bevl**—bevel
- **cel**—cellular
- **cent**—centrifugal
- **chn**—chain
- **cst**—cast
- **ctr**—center
- **cylinders cast, 2 in pairs**
- **cylinders cast, 4 in block**
- **cylinders cast, 3 in threes**
- **cylinders cast, 1 singly**
- **cyl-ends**—cylinder-ends
- **d**—dual
- **d-d**—dry-disk
- **d-p**—dry-plate
- **dplx**—from both motor & driveshaft
- **d-rd**—double reduction
- **d-s**—drive-shaft
- **elec**—electric
- **ext-d-s**—external drive-shaft
- **ext-f-w**—external front wheel
- **ext-g**—external gear
- **ext-jst** — external jack-shaft
- **ext-r-w**—external rear wheel
- **fab**—fabric
- **fin**—finned tube
- **flex**—flexible
- **f-m**—fabric & metal
- **fric**—friction
- **g-p**—gear pump
- **grv**—gravity
- **gset**—from gearset
- **hyd**—hydraulic
- **ind-c**—individual clutch
- **int-g**—internal gear
- **int-g-4** — internal gear drive on 4 wheels
- **int-r-w**—internal rear wheel
- **jst**—unit with jackshaft
- **l**—left
- **l-b**—loose ball
- **lghtg**—lighting only
- **mtr**—unit with motor
- **mt**—metal (wheels)
- **mtl**—metal (universal joint)
- **opt**—optional
- **pist**—piston pump
- **plan**—planetary
- **pln**—plain tube
- **pnu**—pneumatic
- **pres**—pressure
- **prog**—progressive
- **prs**—pressed steel
- **p&s**—pneumatics in front solids in rear
- **p-stl**—pressed steel
- **r**—right
- **r&c**—right & center
- **r-rd**—radius rods
- **rol-c**—rolled channel
- **rol-i**—rolled I-beam
- **selec**—selective
- **s-flex**—semi-flexible
- **s-fr**—sub-frame
- **sht**—sheet
- **s&l**—starting & lighting
- **sl&i-2**—starting, lighting & ignition, 2 unit
- **sol**—solid
- **sprgs**—springs
- **sq-t**—square tube
- **start**—starting only
- **suct**—suction
- **t-arm**—torque arm
- **ther**—thermo-syphon
- **t-p**—two-point
- **t-t**—torsion tube
- **vac**—vacuum
- **wat-tube**—water tube
- **wd**—wood
- **w-d**—multiple disk in oil
- **w-p**—plate in oil
- **wr**—wire
- **zz-t**—zig-zag tube

Trend in Truck Design

(Continued from page 334)

Location of the steering gear at the left is approaching universal adoption, but a little over 5 per cent still have right hand drive. For what reason it is retained by even this number is not apparent, except in the case of cars for export to certain countries, or where a change from a model long manufactured with right hand drive would involve expense not commensurate with the advantage gained, a reason often applying or said to apply in the case of manufacturers who continue a practice long since abandoned by a very large majority of builders.

Pressed steel frames are now employed in the case of about three out of every four models. One in four employs structural steel, due it may be assumed, in most cases at least, to the expense of die equipment, for the structural steel frame seems to offer no advantage except easier length

variation over a well constructed pressed steel frame.

An increasing number of radiators are of the tubular core cast case type. Less than 20 per cent use cellular cores, and these are mostly applied to the light pneumatic tired jobs. About 80 per cent of all models use cast case radiators, while of the remaining 20 per cent about one-third use sheet metal two-thirds pressed steel.

The Hotchkiss drive is employed in about 57 per cent of models as against about 55 per cent in 1920. Nearly 60 per cent of models are fitted with centrifugal type governors—less than last year because fewer trucks are fitting any governor. Quite a number of truck models are fitted with fabric universals exclusively, and a larger number are a combination of fabric and metal universals, but about 80 per cent of all models use only metal joints, though the percentage of fabric joints is increasing.

British Car Practices

By M. W. Bourdon

(See page 322)

PERCENTAGES OF BRITISH CARS INCORPORATING VARIOUS DESIGN FEATURES

Number of Cylinders

4-cylinder ....76.5 per cent
6-cylinder ....16.0 per cent
2-cylinder .... 3.5 per cent
8-cylinder .... 2.5 per cent
3-cylinder .... 1.5 per cent

Cylinder Type

L head ....72.0 per cent
Valve in head......21.5 per cent
Sleeve valve .... 5.0 per cent
Overhead inlet ..... 1.5 per cent

Overhead Valve Drive

Overhead camshaft..57 per cent
Push rods ....43 per cent

Cylinder Casting

Fours in block.......96 per cent
Fours in pairs........ 4 per cent

Cylinder Heads

Integral ....51 per cent
*Detachable ....49 per cent

*Unit cylinder and crankcase 40 per cent.

Piston Material

Cast iron ....70 per cent
Aluminum ....26 per cent
Steel .... 3 per cent
Aluminum and cast iron .... 1 per cent

Connecting Rods

H section ....95 per cent
Tubular .... 5 per cent

Number of Piston Rings

Three ....60 per cent
Two ....30 per cent
More than three.....10 per cent

Wrist Pin

Fixed in piston......52 per cent
Floating ....28 per cent
Fixed in rod.........20 per cent

Lubrication Systems

Trough (circulating splash) ....51 per cent
Hollow shaft (pressure) ....49 per cent

Oil Pump Type

Gear (twin pinion)...70 per cent
Plunger ....21 per cent
Multi plunger .... 5 per cent
Eccentric .... 4 per cent

Fuel Feed

Gravity ....56 per cent
Vacuum ....30 per cent
Pressure ....14 per cent

Water Circulation

Thermosyphon ......48 per cent
Pump ....44 per cent
Assisted thermo-syphon .... 8 per cent

PERCENTAGES OF BRITISH CARS INCORPORATING VARIOUS DESIGN FEATURES

(Continued)

Radiator Core
Cellular ....68 per cent
Tubular ....32 per cent

Ignition
Magneto ....89 per cent
Battery .... 6 per cent
Magneto and battery 5 per cent

Distribution Gearing
Chain ....55 per cent
Skew pinion ....30 per cent
Straight pinion ....13 per cent
Worm .... 2 per cent

Chain Distribution
Non-adjustable ....51 per cent
Adjustable ....49 per cent

Clutches
Cone ....61 per cent
Single disc ....27 per cent
Multiplate .... 2 per cent

Gearset Mounting
Amidships ....68 per cent
On engine ....25 per cent
On axle .... 4 per cent
On torque tube.... 3 per cent

Number of Gears Change
Four speeds....50 per cent
Three speeds....50 per cent

Propeller Shafts
Open ....50 per cent
Enclosed ....45 per cent
Semi-enclosed .... 5 per cent

Propeller Shaft Joints
Disk ....34 per cent
Plain bearing star...31 per cent
Sliding block (pot)...27 per cent
Ball or roller star.... 8 per cent

Final Drives
Spiral bevel ....46 per cent
Bevel ....28 per cent
Worm ....26 per cent

Brake Location
Both on rear wheels.61 per cent
Transmission and wheels ....39 per cent
Transmission brakes:
External ....81 per cent
Internal ....19 per cent

Wheel Brakes
Internal ....90 per cent
External ....10 per cent

Rear Springs
Half elliptic ....48 per cent
Cantilever ....21 per cent
Quarter elliptic....16 per cent
Three-quarter elliptic.15 per cent

Front Springs
Half elliptic ....88 per cent
Quarter elliptic ....10 per cent
Cantilever .... 1 per cent
Transverse .... 1 per cent

Wheels
Pressed steel hollow spoked ....56 per cent
Wire ....20 per cent
Disk ....20 per cent
Wood .... 4 per cent

†Gasoline electric. *Six Wheeler.

Magneto ignition on all trucks; fixed spark timing on 9, 10, 19, 20, 52, 53; honeycomb radiator, 10; plain tube, 25; others flanged tube; sheet metal radiator shell, 9, 10; other radiator shells cast. Vacuum fuel feed, 10, 25, 43, 51; others gravity feed; unit power plants, 7, 10; pneumatic tires, 8, 9, 10; optional tire equipment, 1, 3, 4, 12, 45, 58, 59, 60; other tire equipment solid. All hand brakes internal expanding.

Percentage of Various Design Features

Cylinder Number

All four-cylinders, except one make with one model.

Cylinder Type

L head ....71 per cent
T head ....12 per cent
Valve in head ....13 per cent
Sleeve valve .... 2 per cent
Overhead inlet .... 2 per cent

Cylinder Heads

Integral ....80 per cent
Detachable ....20 per cent

Lubricating Systems

Hollow shaft (pressure).....57 per cent
Trough (circulating splash).43 per cent

Fuel Feed

Gravity ....93 per cent
Vacuum .... 7 per cent

Water Circulation

Pump ....85 per cent
Thermo-syphon ....12 per cent
Assisted thermo-syphon ..... 3 per cent

Radiators

Vertical tubes ....84 per cent
Horizontal tubes ....16 per cent

Ignition

Magneto ....100 per cent
Variable timing .... 90 per cent
Impulse starter .... 10 per cent

Tendencies in British Truck Design in 1921

Only a few makers build trucks of less than 3000 lb. capacity. Steam trucks of 5-ton capacity hauling trailers and using either solid or liquid fuel compete with gasoline propelled trucks. Use of worm drive, pressed steel frame, and cast wheels increasing. Magneto ignition universal.

By M. W. Bourdon

THE manufacturers of British trucks are adopting a very conservative attitude on the subject of pneumatic tires for loads above 3500 lb. and not one of them is yet prepared to recommend either giant or twin pneumatics for bigger loads. Several are experimenting on their own transport vehicles, but are not yet inclined to advise buyers to discard solids. An exception must be made, however, of passenger-carrying vehicles—especially charabancs—with seating for from 18 to 32 passengers. In such cases pneumatics are advised, tentatively and with many reservations, it is true. But there is an inclination towards twin pneumatics for the rear wheels in place of giant singles, and the most favored make is the Michelin on the same firm's disk wheels. Goodyear is, nevertheless, pushing giants very hard and will no doubt make a gradual and an increasing impression on the potential market.

As might be gathered from what has been said, British truck makers are not yet making plans for a special chassis more suited to the use of pneumatics than the existing types. The great majority of firms spread themselves on trucks for 3 to 5 ton (say, 6700 lb. and 11,000 lb.) loads, comparatively few making smaller chassis and only isolated plants turning out vehicles for 30 cwt. and less.

Austin is the most prominent new-comer in the latter field with a chassis having the 20 h.p. engine and gearset unit designed originally for the post-war Austin passenger car. Of its size and type it is the cheapest British truck. There is no truck or light van made to compete with the Ford, for though a few firms have modified passenger car and taxicab chassis for light delivery service, their prices are far above that of the one-ton Ford.

The steam truck for loads of 5 tons on its own superstructure and 2 or 3 tons additional on a trailer is very popular among users for certain classes of work. It is not only, as it was at one time, confined to short journeys and dock and rail service, but several of the many transport companies which have sprung up all over the country since the war utilize this type of vehicle for runs up to 200 miles away from headquarters. It has a two-man control, for, clearly, stoking with solid fuel cannot be done by the driver. The majority are now fitted with solid rubber tires instead of the iron shod wheels which gave them a legal speed of only 5 m.p.h. and an economical speed of less than double that if the drivers cared to risk it. With rubber tires its legal speed is 8 m.p.h., but this is very frequently exceeded, speeds of 28 to 30 m.p.h. being maintained mile after mile on slightly falling gradients.

The internal combustion engined truck is, therefore, feeling the competition of the steamer more than previously, and the need for stops with the latter to replenish the water supply at least every 30 miles is, by many owners, considered compensated for by the lower cost of fuel consumed. Serious attempts are now being made to utilize liquid fuel for their burners, and although this shows approximately 20 per cent increase in cost at present as compared with coal, is offset by the greater convenience, time saved in filling up, and better average speed owing to the driver being able to maintain steam pressure more easily under varying conditions of running.

Reverting to gasoline trucks, with which the accompanying table deals exclusively, the most marked variations since the war are the wider use of pressed steel frame members in lieu of channel section rolled steel; the discarding of side chains for final drive in favor, as a rule, of the worm; the increasing use of the fabric disk type of universal joint; and the great popularity of the cast steel hollow spoke wheel. Disk wheels have not proved so durable as was originally anticipated; considerable trouble has been experienced with the loosening of rivets, and although Thornycroft, among the important makers, uses them exclusively, most of the other well-known firms are gradually dropping them. At present 55 per cent of British trucks have the cast hollow spoked type, 21 per cent disk (the latter including some of the light delivery vans), 15 per cent cast steel, solid spoked, and 9 per cent wood and miscellaneous.

The flitch plate frame still finds adherents in Daimler and A. E. C., though only in one model of the latter; 77 per cent of chassis have pressed steel side members and 16 per cent rolled steel channel. Of both pressed and rolled, 10 per cent have the channel facing outward, for with this arrangement, it is claimed, mounting of cross members, sub frames and main components is facilitated.

The T-head cylinder construction, which, before the war, was considerably favored, has been very largely discarded, and 71 per cent of engines now have L-heads. Nevertheless, one or two of the most prominent firms still arrange the valves on both sides, notably Dennis and Thornycroft, the latter in three models out of four. Seventy-seven per cent of cylinders are pair cast, but only 20 per cent have detachable heads. The 23 per cent of block cast cylinders all occur in chassis of a load capacity of 2 tons or under.

The following are average bores and strokes for British trucks of the load capacities given: 4500 lb., 3⅞ x 5½ in.; 6700 lb., 4¼ x 5½ in.; 9000 lb., 4⅝ x 5¾ in.; 11,000 lb., 4¾ x 6 in.

Frequently, however, makers whose range includes chassis with load capacity from 6700-11,000 lb., utilize the same size of engine for two or three models. For instance, Thornycroft uses a 4½ x 6 engine for three sizes,

Trend of Tractor Design as Revealed by Statistics for 1921 Models

Fewer manufacturers are making creeper type machines. Average piston displacement has decreased but is balanced by increase in piston speed. Fewer two-cylinder engines are used. Marked increase in the percentage of disk clutches. No material change in number of speeds.

By P. M. Heldt

IN order to get a concrete idea of trends in farm tractor design, we have analyzed the tractor specification tables for 1919, 1920 and 1921, and present the results herewith, in tabular form. Comparing the figures for 1921 with those for 1920, the first thing that stands out is a large decrease in the percentage of creeper type tractors. This, of course, is due to the fact that numbers of the creeper tractors listed last year were hardly beyond the experimental stage and never got onto a real production basis. Those firms in the creeper type tractor field which were really producing last year are still doing business. However, the enthusiasm with which the creeper type was taken up by newcomers in the industry last year has received something of a check.

In analyzing the specification sheets it was considered advisable in many cases to see how practice varied in the different capacity classes of tractors. In doing this a difficulty was introduced by the fact that quite a number of tractors now have a double rating, such as 2-3 plow or 3-4 plow. It was decided to use the lower rating for the purpose of this analysis and count the 2-3 plow tractors, for instance, with the 2-plow tractors.

There has been no material change in the distribution between the different classes of the tractors listed. The single plow class, which comprises the garden tractors, is slightly larger and the class of tractors for five or more plows slightly smaller; also the three-plow class does not predominate numerically to the same extent as last year, but on the whole the shifting from one capacity class to another has not been pronounced.

Average piston displacements in all classes have decreased, in the 2-plow class about 10 per cent, in the 3-plow class nearly the same, and in the 4-plow class about 8.5 per cent. No doubt this is largely balanced by an increase in piston speeds. The average piston speed of all four-cylinder engines without regard to plow capacity was found to have increased 2½ per cent.

The percentage of single-cylinder engines has increased, due to the fact that most of the garden tractors recently developed have that type of engine, but these engines are vertical and not exceptionally slow and heavy. The two-cylinder type shows a distinct loss, whereas each of the other three types used shows a gain. There is also a slight decline in the proportion of horizontal engines. On the whole the types of engine used remain very much the same.

There has been no change in the governor situation. A few makes have no governor. The hydraulic and electric types of governor are used on one make of tractor each, and all the rest of the tractors have centrifugal governors. The methods of cylinder casting remain substantially the same, though the block cast type shows a slight gain in popularity.

It was considered desirable to get a comparative figure for engine weight, and the average weights per cubic inch displacement and per belt horsepower. The average of all 1920 engines was found to be 2.69 lb. per cu. in. displacement. However, as the engines considered included some very small ones used on garden tractors, and also some very large ones used on the mammoth 30-60 and 40-80 hp. tractors, it was considered a more logical procedure to average the weights per cu. in. displacement for all engines between 250 and 500 cu. in. piston displacement, which includes practically all of the 2 and 3-plow and the majority of the modern 4-plow tractors. This average was found to be 2.64 lb. per cu. in. displacement, and therefore does not differ much from the general average. The average weight for all engines in respect to rated belt horsepower was found to be 39 lb., while that of engines between 250 and 500 cu. in. displacement was 37.1 lb.

Gravity fuel feed is very much in the lead in tractor practice. Pump feed is used in a number of tractors which have engines of a type similar to those used in stationary practice. The sponsors of vacuum feed have secured a foothold in the tractor industry but little more. The proportions are substantially the same as last year.

Practice in clutches has changed materially. Unfortunately, many concerns in filling out the specification blank do not give the type of clutch, and this leaves the percentage values obtained somewhat uncertain. Disk clutches, which constituted only 48 per cent of the whole in 1920, represented 60 per cent of the total in 1921. This is easily explained, as practically all stock clutches for tractors are of the disk or plate type. The chief competing type is the shoe clutch, which is used mainly by firms which entered the tractor business from the implement industry and manufacture their own clutches. This type of clutch is comparatively bulky and does not lend itself well to enclosure, so the clutches on the newer designs of completely enclosed tractors are practically all of the disk or plate type, the few exceptions being cone clutches.

There has been no great change in respect to the number of gear speeds provided. Slight gains are shown for the two and three-speed tractors and equivalent losses by the single and multi-speed machines. There appeared to be quite a strong tendency in the course of the year to go to three-speeds for three and four-plow tractors, but the figures now available do not bear out this impression. While the three-speed machine has gained somewhat, its gain is no greater than that of the two-speed.

Belt speeds average very close to the standard of 2600

ft. p.m. adopted by the S. A. E. some years ago, the average for different classes going up somewhat with the plow capacity. The average wheelbase of the two and three-plow tractors has decreased, whereas that of the four-plow tractors has increased.

The relation between knuckle steering and axle steering remains the same. Of the new tractors that have come out during the year 1920 a majority have been of the frameless type. The average diameter of the driving wheels remains substantially the same for two and three-plow tractors, but has come down by 2 in. in the case of four-plow tractors. An appreciable decrease in weight is shown for each capacity class of tractor.

Four-plow tractors	6,050 lb.	7,800 lb.	7,461 lb.

*It should be noted that the figures given in this table are based upon specifications published in AUTOMOTIVE INDUSTRIES, this data being compiled from replies to questionnaires sent out for the purpose. In some cases the complete data requested is not furnished, hence the figures given are based upon returns actually made. For example, if 60 out of 100 tractors are reported to have vertical engines and 30 to have horizontal engines (10 makes failing to give data on this point), the table would show 66.7 per cent vertical engines and 33.3 per cent horizontal, the assumption being that of the 10 not reporting the percentage of vertical and horizontal will be the same as in the case of those reporting.

Forest Fire Patrol Activities from March Field

A CONSOLIDATED report of forest fire patrol activities carried on from March Field from May 19th to October 31, 1920, gives some interesting statistics.

Total number of flights	314
Total flying time	1,143 hrs. 38 min.
Total gallons gasoline consumed	19,990
Total gallons of oil consumed	1,222¼
Area of square miles covered	131,479,493
Total miles flown	108,920
Total number of fires discovered	131
Total number of planes flown (DH-4B's)	6
Total number of minor accidents	1
Total number of major accidents	None

This patrol was carried on under the direction of Captain Ernest Clark, officer in charge of flying at this field. Pilots were graduate cadets from this school. C. R. Benton, forester, was stationed at the field during the patrol season, relaying information about fires from the radio station to the various rangers in the mountain reserves.

Gas Tractor Engine Exports—Increase from 1914 to 1920

Large business with Canada continues during 1920, while nearly 20 per cent of engines exported go to South American countries.

AGAIN of 10 per cent in the number of gas tractor engines exported from the United States is recorded for 1920 over the 1919 figures. During the last year 22,481 engines were sent to foreign countries, 2045 more than were exported during the previous year.

Canada received the largest number of these exported engines during 1920, its total being 9606, while the Philippine Islands came next with a total of 1461. A few of the countries to receive the largest number of engines during the past year are:

Canada	9,606
France	2,071
Philippine Islands	1,461
England	977
Argentina	920
Peru	701
Australia	600
Spain	492

To South America as a whole went 4295 engines, comprising slightly over 19 per cent of the total gas tractor engine exports. The value of the engines sent to South America was $2,218,464 which is about 9.9 per cent of the total value of gas tractor engines exported during the year 1920.

This indicates that the South American countries were larger buyers of light gas tractor engines than the rest of the world as a whole, and that the market for small engines is better than for heavy ones in this section. This is further borne out by the fact that the average value of all engines exported in 1920 was $978, while the average value of those sent to South America alone was but $516.

Following is the average value of gas tractor engines exported each year:

1914	$1,965
1915	2,152
1916	2,040
1917	1,320
1918	1,018
1919	980
1920	978

This shows a steady decrease in the average price

since 1915, indicating that there has been an increased sale of lighter engines, and that it is to this class of gas tractor engine that much of the increased export trade in this field may be attributed.

The value of tractor engine exports increased in 1920 to $21,965,959, a gain of $1,937,-787 over 1919. This is an increase of 9.79 per cent. The enormous jump in the value of gas tractor engine exports during the last seven years can be readily perceived, when it is noted that a value gain of 1430 per cent has been made during that time.

It is interesting to note which countries have bought the most from U. S. gas tractor engine manufacturers during the seven years covered by the accompanying table. As might be expected, such an examination shows the largest business to have been done in general with the largest countries. The first five are in order as follows:

Canada	$27,819,925
England	19,673,483
France	12,332,549
Mexico	11,447,396
Italy	8,864,209

The large business with Canada may be attributed to its proximity and the freedom of intercourse between U. S. and Canada during the war period. The large Mexican total, it will be noted, is due rather to a steady business each year, rather than to extremely large sales in any one year. This steady business has remained on a high level since 1918 and has reached a new high mark in 1920.

British Agricultural Tractor Practice in 1921

No standard type yet developed. All engines are vertical but some are of low speed type and one uses fuel injection. Two speed gearset usually provided. Creeper types in favor with British farmers.

By M. W. Bourdon

THE accompanying list of agricultural tractors made in Great Britain indicates that the manufacture of these is a very extensive industry. The lead set by Ford has been followed by Austin, but this maker is practically alone among British manufacturers in adopting a comparatively high-speed lightweight motor in a compact and lightweight frameless machine with four wheels and two tracks.

There is actually no one type of tractor which can be said to represent general practice among British makers, but there is a tendency to favor a somewhat heavier machine than the Ford or Austin, with a larger engine than either of the latter. The new makes following these lines which have created a good impression are the Martin tractor, as distinct from the self-contained plow of that name, and the Peterborough, the latter having a Ricardo trunk piston engine. The British Wallis also exemplifies this type; it is made by a prominent engineering firm, Ruston, Proctor & Co., Lincoln, and has many modifications compared with the American Wallis, making it more compatible with British ideas. It is a four-wheeled machine with two tracks, and secured the highest award in its class in the British Tractor Trials last September.

There is no British tractor manufacturer using a horizontal engine, but the low speed of revolution which the horizontal type suggests occurs in the Sanderson. The Blackstone, which has a motor also with a normal speed of 750 r.p.m., is of a special type with three cylinders and low-tension magneto ignition. It also has a special vaporizing system in which the fuel is injected directly into the cylinders, the latter being previously charged with air under pressure. This engine is fitted with a compressed air starter, but generally speaking the Blackstone tractor has yet to prove its serviceability in practical use. The Glasgow three-wheel drive three-track machine, with a Continental engine, is making a good name for itself and is slowly getting into production, though it is the intention eventually to fit it with an Argyll-Burt single sleeve motor and to quadruple at least the present output of approximately 12 to 15 tractors per week.

There is a tendency to fit more efficient brakes to British tractors, the latter in several cases being provided with expanding shoes within wheel drums, these supplementing a block applying to the belt pulley.

Except in those machines designed for road haulage as well as work on the land, two forward speeds are most generally provided; but in regard to final drive there is no uniformity, practically every available system being utilized by one maker or another. The chain track machine is represented by only one example that counts, namely, the Martin self-contained plow. Both the Crawley and the Fowler, other self-contained implements, are of the wheeled type with the motor balanced against the plow, respectively front and back of the main axle. The chain track machine does not find much favor among British farmers, and it is anticipated that before long this type will not be produced by any British agricultural tractor manufacturer.

The Trend of Airplane Design

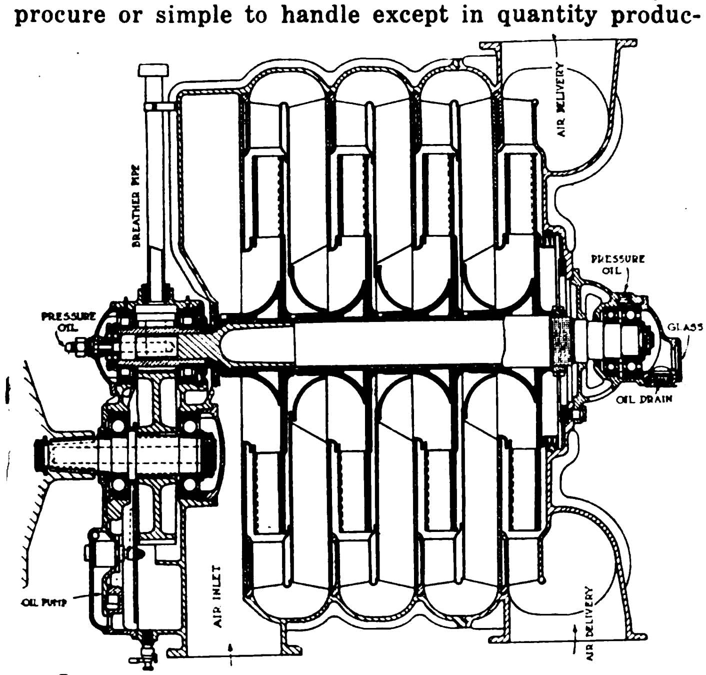
Those who recall the airplane trend article in the Statistical number of 1920 will be especially interested in the opinions on this page. The accuracy of last year's forecast makes no recommendation necessary this year.

THE year just past has been a period of re-adjustment for aircraft. The requirements of commercial aviation have been largely filled by surplus war material. General business conditions have made these requirements small. Designers have been studying the characteristics of planes developed during the war and the data accumulated is being incorporated in new designs. Those considering aviation a get-rick-quick game have left. Those remaining have chosen aviation as a life proposition, and have set out seriously to solve its problems. With the return of normal times the industry will be on a firm basis, ready to expand conservatively as conditions warrant.

Foreign Influences.—It is unfortunate, but true, that a tendency has existed to belittle American designs as compared with Continental designs. Since the war it has been possible to study these designs in direct comparison with our own. And all things considered—ease of manufacture, upkeep, air qualities, life—the coming conclusion is that American designs and American methods are best for Americans.

Early in the year the foreign all-metal monoplane led the field. From the apparent advantages, here was a machine that was fireproof, durable, efficient and well adapted to commercial use. Several of them, however, have been burned, and the problem of holding thin metal sections together under vibration has not been solved.

Startled by the evident advantages of all metal construction, American designers and constructors hastened to experiment with it in their own designs. It was found that the best metal—duralumin—was not easy to procure or simple to handle except in quantity production. Quantity production is at present lacking and the advantages of this construction are not sufficient for its extensive use at the present time.



Latest design of the Brown-Boveri blower for 1200-*hp. installation*

Metal Construction.—Metal construction, however, will increase, as American manufacturers become more familiar with its manufacture and airplane builders are organized to handle fabrication. There are serious construction problems to solve. In the meantime wood and metal construction will hold its own.

Monoplane, Biplane or Triplane.—Whether an airplane should have one, two or three supporting surfaces is still an open question. It can be no more arbitrarily settled than can the proper number of cylinders for a motor car engine. The present tendency, however, is toward internally braced monoplane design.

The internally braced monoplane is the cleanest and most efficient aerodynamic structure. Thick wing sections have been and are being developed that are extremely efficient. One interesting example of this type is the Stout bat-wing monoplane. A small commercial machine, having a veneer covered internally braced wing has been constructed and flown. A similar military machine of duralumin is in process. The feature of this type plane is that all longitudinal sections are lifting sections.

There is at present a slight trend toward the parasol type of monoplane—internally or externally braced. This construction provides maximum wing area for the span; permits continuous wing structure and provides good vision.

The majority of designers still favor the biplane type because of the combination of desirable features—moderate span, good air characteristics, adaptability to wooden construction and familiarity. This type will continue popular. At present all speed and distance records are held by biplanes, both here and abroad.

One of the fastest and cleanest of American planes—the Kirkham—is a triplane, and the large flying boat under construction by the Navy Department is reported to be a triplane.

Large Planes.—The trend toward large planes seems to be dying down somewhat. The development is retarded by lack of large power units and suitable landing fields. Possibly the largest under construction is the C.B. flying boat being made by the Navy Department. This will weigh around 70,000 pounds when complete, and be powered by groups of Liberty engines. The Army is also reported to have a large plane under construction. Under present conditions the reasonable upper limit of size appears to be approximately 100 ft. span and 5-7 tons total weight, depending on whether it is a land or seaplane.

Small Planes.—Small, that is, really small planes, have not proven as popular as was expected. Such planes are ordinarily without much purpose, and few experienced flyers fly simply for the sake of flying. There is, however, one comparatively small plane—the Sperry Mes-

British Motorcycle Practice

Lightweight 2½ horsepower machine gaining in popularity, because of economy and the higher tax on heavy machines. Many machines have stock engine and gearset. Single-cylinder engine predominates. Two-cylinder opposed also popular. 52 per cent of gearsets are three speed.

By M. W. Bourdon

THE outstanding feature of the British motorcycle industry at the moment is the large and increasing number of makers turning out lightweight machines with single-cylinder two-stroke engines of approximately 2½ hp. with belt, or chain and belt transmission. This feature is accounted for by two facts, (1) the demand for a machine economical in upkeep and fuel and (2) the new scale of taxation which came into force on Jan. 1. The latter imposes an annual tax of $7.50 on machines weighing not more than 200 lb. and double that amount on those over that weight, sidecars for either class being taxed $5 extra.

The two-stroke engine for these light machines is favored on account of its simplicity and low cost of production, though the four-stroke type is also widely used for low-powered mounts; in fact, if the class be extended to include as a maximum the 2¾ hp. machine, it will be found that 55 per cent have four-stroke engines. But that extra ¼ hp. usually means that the machine is carried into another class in performance, price and taxation rating.

Only 38 per cent of makers used stock engines, and of these J. A. Prestwich (J.A.P. engines) supplies 60 per cent; a similar percentage of the small two-stroke stock motors are of Villiers make and have a flywheel magneto for ignition.

The single-cylinder engine still predominates in point of numbers on British motorcycles generally; taking all sizes, it appears on 57 per cent, the 43 per cent of twins being made up of 25 per cent with horizontally opposed cylinders and 75 per cent Vee. The latter are almost completely out of favor in sizes under 5-6 hp., the at one time popular 3½-4½ hp. Vee twin having been superseded by the horizontally opposed type, which is constantly finding new adherents. Non-detachable cylinder heads are the rule, only 24 per cent being detachable, and most of these of the horizontal twin type.

The majority of crankshaft bearings are plain bushes, but ball and roller types are both increasing in favor, though not infrequently only one of the latter is used and that on the belt pulley or chain sprocket end of the shaft with a plain bearing at the other end. Roller or ball bearings are also being more widely used for the connecting rod big end. The table shows that some 36 per cent of engines have roller bearings at this point.

The difficulty of keeping the overall height of vertical and Vee engines within reasonable bounds doubtless accounts very largely for the paucity of overhead valve gear. Only 6 per cent of engines have both valves in the head, and these are mostly horizontal twins. Superimposed valves also account for 6 per cent. Thus the majority (68 per cent) have side valves, though among these are some engines with the exhaust and inlet valves arranged around the cylinder at 90 deg. from one another, the exhaust being arranged in front of the cylinder to submit it to the best cooling effect from air draught. With only one or two notable exceptions (for example, the two-cylinder water-cooled Scott and the 4½ hp. Dunelt) the valveless engines are the small two-stroke motors already referred to. But both the Scott and the Dunelt have earned excellent reputations despite (or possibly on account of) their two-stroke engines, and have shown that there is no good reason why the two-stroke type should be confined to the lightweights.

Almost all engines have cast iron pistons, only 2 per cent being provided with aluminum. But this uniformity does not extend to lubrication systems, where there is quite a remarkable diversity of practice. Splash lubrication pure and simple is held sufficiently effective in 73 per cent of engines, the feed from the oil compartment of the frame tank being usually maintained by a pump, the plunger of which is lifted by hand against a spring which returns it gradually to its normal position, driving out the oil through a sight drip feed. Some splash systems embody a modification consisting of a mechanically operated pump in the crankcase which has a big ratio of reduction in speed (30-40 to 1) in its drive from the crankshaft. This pump draws oil from the tank and discharges it in small quantities into the crank chamber, where splash is depended upon.

The "petroil" lubricating system (oil mixed with fuel) for two-stroke motors is disappearing. Triumph (one of the largest firms) retains it for the present, but in most other engines of this type a drip feed and splash or drips led to a hollow crankshaft are displacing it.

Ninety-five per cent of the clutches used are of the plate or disk type. Two-speed gearsets for machines up to 2½ hp. almost invariably have only a single driven plate, but the larger machines have the multi-plate type, generally with 3 or 4 driven units. Fabric facings running dry are found in 90 per cent single and multi-plate, only 10 per cent being metal to metal in an oil bath. Clutch control is by hand on 86 per cent of machines, and this is accounted for by the fact that even the largest and most highly powered are double-purpose machines; when used in solo form the pedal controlled clutch is disliked, owing to the impossibility of straddling with both feet on the ground until the machine moves off with the full engagement of the clutch.

The majority (55 per cent) of gearsets are stock jobs and 80 per cent of these are Sturmey-Archer, either two or three-speed with the clutch integral. Three-speeds form 54 per cent of the total, two-speeds 32 per cent, 7 per cent have a single ratio with belt drive and 7 per cent belt drive with variable pulley; two of the best known makes—Rudge-Whitworth and Zenith—have the latter system, even on 6-8 hp. models. Only 9 per cent of gearsets are arranged as a unit with the engine, this being partly due to the popularity of J.A.P. engines and Sturmey-Archer gearsets, neither of which is designed for or adaptable to unit construction.

The fact that, with few exceptions, the large number of

two-stroke lightweights have chain and belt drive accounts for the latter system being the most widely used (48 per cent). This system, consisting of a primary chain from crankshaft to gearset and a Vee belt from the latter to the rear wheel, is also used on all powers of machines up to the largest, but nevertheless the all-chain transmission is increasing in popularity through the range above 2½ hp. Rarely is the final chain protected by more than a top mud shield, but the primary chain is usually enclosed and not infrequently lubricated by only vapor discharged from an extension of the crankcase breather pipe.

Rear sprung frames are showing no rapid increase, not because there is any falling off in the demand for better protection against road shock, but on account of the additional cost and weight. As regards the first, crudity in design is largely the cause, for some of the arrangements are involved beyond measure. That a simple but effective rear spring can be provided without lack of lateral stability (the bugbear of designers) is evident from one or two exceptions to the general rule—the Beardmore-Precision, for example, wherein a cantilever spring located behind and loosely speaking, parallel with the saddle tube, is used. The drawback of undue additional weight has not, however, been overcome even in these exceptional cases, and in view of the inherent stability and low weight of the rigid tubular construction, it is not difficult to realize why the extra weight of a sprung frame is far more than that represented by the actual spring or springs; the lateral flexibility of the springs must be counteracted by means which considerably increase the weight of the tubular portions.

Much the same difficulty has been experienced by those designers who have attempted to employ pressed steel frames; they have found that to retain the lateral rigidity and torsional strength of the tubular construction has necessitated an increase of frame weight up to 80 per cent. While the pressed steel form is obviously desirable from several standpoints, the tubular frame unquestionably has the advantage in low weight combined with stability.

Readily detachable and interchangeable wheels have not increased to any marked extent during the past twelve months, and they appear almost entirely in large sidecar machines, and by no means invariably in these. Of the non-interchangeable wheels 15 per cent have knock-out rear spindles, enabling the back wheel to be quickly detached for tire removal, without disturbing the transmission details or brake gear.

In regard to brakes, the horseshoe tire rim type still predominates (76 per cent) on front wheels, and the V block applying to the belt rim on a brake rim on the rear wheels. But for both back and front the expanding shoe or contracting band applying to a 10 to 12 in. drum is gradually gaining ground; the former, for example, is now used on 25 per cent of machines.

British motorcycle design has not shown any pronounced improvement, except in detail and equipment, since the war. Makers during the past two years have devoted all their energies to securing output and have meanwhile, in the majority of cases, neglected to evolve new designs differing to any marked extent from pre-war standards. That they have thus restricted their market there can be no question, for they have as yet made little or no attempt to cater to the vast number of potential purchasers who desire a machine which they can use for business purposes without being compelled, for the sake of cleanliness and warmth, to wear special clothing. It has been computed that this market is as large as that which calls for the present type of machine, and yet, with the exception of scooters, nothing has been offered to the men who desire a means of getting to and from their home and city office or from one business house to another in normal attire. But there are indications suggesting that a few firms have realized possibilities in this direction, and it will be surprising if during the next twelve months there are not developments representing a new starting point for a section of the industry.

Tendencies in British Truck Design

(*Continued from page* 354)

although the chassis of the larger capacity trucks is stiffer and the gear ratios are varied. The 3 tonner (6700 lb.), for instance, has a back axle gear ratio of 7.25 to 1, while the 5 to 6 tonner has a ratio of 10.3 to 1.

The wheel tracks of these heavier types vary considerably, running from 65 in. in the case of Leyland to 72 in.

Worm final drive has increased in popularity very considerably of late, and 52 per cent of chassis now have this form of transmission as compared with 23 per cent chains and 20 per cent double reduction. Only 5 per cent have straight bevel gearing and no British trucks use an internal gear final drive. Open propeller shafts are favored in the proportion of 69 per cent as compared with 13 per cent enclosed and 18 per cent semi-enclosed. The fabric disk joint at both ends of an open shaft occurs in 32 per cent of trucks being equalled in popularity only by the arrangement having a star joint at one end and a sliding pot joint at the other, which occurs in 33 per cent. In star joints plain bushes are generally used, though 11 per cent of all universals have ball bearings. There are only 13 per cent of trucks with both brakes applying to the back wheels; none of these are external brakes, though among the 77 per cent of vehicles in which a transmission brake occurs the vast majority have external shoes.

In regard to engine lubrication, 43 per cent of engines listed have the trough system as compared with 57 per cent hollow shaft. The trough system usually includes direct leads to the main crankshaft bearings and sometimes to the camshaft as well. Magneto ignition is universal, with variable hand timing in 90 per cent. Impulse starters do not, however, show up prominently, only 6 chassis being equipped with them as standard. Pump water circulation occurs in 85 per cent of engines, thermo-syphon in 12 per cent and thermo-syphon assisted by a belt-driven water accelerator in 3 per cent. The thermo-syphon system is not, however, confined to the smaller trucks, for the whole range of Commer cars, including the largest type with a load capacity of 11,000 lb., has the water naturally circulated in an engine with a bore and stroke of 4½ x 5½ in. No cellular radiators are used except for the lightest delivery vans, 84 per cent of trucks proper having vertical tubes, the remainder having horizontal tubes. With one exception, the Guy with a 5500 to 6000 lb. load capacity, all have gilled tubes, the exception having a bank of ⅜ plain brass tubes vertically arranged. Fifty-seven per cent of British trucks have no governor as part of the standard equipment, while only 10 per cent have electric lighting included, though of the remainder, 50 per cent have provision for a lighting generator.

Cone clutches predominate (79 per cent as compared with 19 per cent disk and 2 per cent multiple-disk). All gearsets except the Austin are separately mounted. Ball bearings for gearsets are general, and in 90 per cent the gear shafts are side by side.

Motorcycle Records

The M. & A. T. A. (Motorcycle & Allied Trades Association) is the governing body for motorcycle competition in the United States. Its records on Jan. 1, 1921, are as follows:

COMPETITIVE RECORDS

These records are for the best time made in M. & A. T. A. competition for the distance, regardless of the nature of the course and whether or not a National Championship was involved:

SOLO, 61 CUBIC INCHES

One Mile—45 2-5 secs.—Made by Gene Walker, Indian, Cleveland, Ohio, Sept. 19, 1920. (Mile dirt track.)

Two Miles—1:14 3-5—Made by Otto Walker, Harley-Davidson, Sheepshead Bay, N. Y., Oct. 11, 1919. (Two-mile speedway.)

Five Miles—3:50 4-5—Made by Gene Walker, Indian, Readville, Mass., Oct. 23, 1920. (Mile dirt track.)

Ten Miles—6:19 2-5—Made by Gene Walker, Indian, Sheepshead Bay, N. Y., Oct. 11, 1919. (Two-mile board speedway.)

Twenty-five Miles—18:40 3-5—Made by Gene Walker, Indian, Grand Island, Nev., July 4, 1919. (One and four-fifths mile dirt track.)

Fifty Miles—32:57 2-5—Made by Ray Weishaar, Harley-Davidson, Sheepshead Bay, N. Y., Oct. 11, 1919. (Two-mile board speedway.)

One Hundred Miles—1:07:57—Made by Albert Burns, Harley-Davidson, Sheepshead Bay, N. Y., Oct. 11, 1919. (Two-mile board speedway.)

Two Hundred Miles—2:26:46—Made by Maldwyn Jones, Harley-Davidson, Dodge City, Kan., July 5, 1920. (Two-mile dirt speedway.)

Three Hundred Miles—3:40:04 4-5—Made by Jim Davis, Harley-Davidson, Dodge City, Kan., July 5, 1920. (Two-mile dirt speedway.)

SIDECAR, 61 CUBIC INCHES

One Mile—1:13 3-5—Made by Lester Foote, Harley-Davidson, Greeley, Col., Sept. 17, 1920. (Half mile dirt track.)

Two Miles—1:49 1-5—Made by Jiggs Price, Harley-Davidson, Readville, Mass., Oct. 23, 1920. (Mile dirt track.)

Five Miles—4:35 3-5—Made by Jiggs Price, Harley-Davidson, Cleveland, Ohio, Sept. 19, 1920. (Mile dirt track.)

Ten Miles—8:15 3-5—Made by Sam Riddle, Indian, Sheepshead Bay, N. Y., Oct. 11, 1919. (Two-mile board speedway.)

Twenty-five Miles—20:36 2-5—Made by Teddy Carroll, Indian, Sheepshead, Bay, N. Y., Oct. 11, 1919. (Two-mile board speedway.)

NON-COMPETITIVE RECORDS
STRAIGHTAWAY RECORDS

(Made under M. & A. T. A. Sanction)

Made at Daytona Beach, Fla., in 1920, not in competition. Both professional and amateur classifications. All electrically timed and checked and certified.

# of American Motorcycles for 1921.

PROFESSIONAL, SOLO 61

(8-Valve Motors)—By Gene Walker, Indian, April 14-15, 1920. Kilometer—19:32 sec. One mile—31:53 sec. Two miles—1:04:45. Five miles—2:45:62.

Both Ways of Course—Kilometer—22:16 North; 21:04 South; 21:60 average. One mile—35:78 North; 33:62 South; 34:70 average.

PROFESSIONAL, SOLO 61

(Pocket Valve Motors)—By Gene Walker, Indian, April 14-15, 1920. Kilometer—21:15 sec. One mile—34:20 sec. Two miles—1:09:71. Five miles—3:04:70.

Both Ways of Course—Kilometer—23:83 North; 22:11 South; 22:96 average. One mile—38:00 North; 34:92 South; 22:96 average.

PROFESSIONAL, SOLO 30.50

(4-Valve Motors)—By Gene Walker, Indian, April 14-15, 1920. Kilometer—25:80 sec. One mile—40:98 sec. Two miles—1:23:03. Five miles—3:30:11.

Both Ways of Course—Kilometer—28:30 North; 26:12 South; 27:21 average. One mile—45:63 North; 42:08 South; 43:85 average.

PROFESSIONAL, SIDECAR 61

(8-Valve Motors)—By Leslie Parkhurst, Harley-Davidson, Feb. 17, 1920. Kilometer—26:54 sec. One mile—42:81 sec. Two miles—1:25:69. Five miles—3:34:52.

Both Ways of Course—Kilometer—26:54 North; 44:88 South; 43:85 average.

1920 NATIONAL CHAMPIONSHIPS

One Mile, 61—Won by Gene Walker, Indian, Cleveland, Ohio, Sept. 9. Time, 45 2-5 sec.

One Mile, 30:50—Won by Gene Walker, Indian, Akron, Ohio, Aug. 1. Time, 1:06.

One Mile, Sidecar—Won by Lester Foote, Harley-Davidson, Greeley, Colo., Sept. 17. Time 1:13 3-5.

Two Miles, 61—Won by Gene Walker, Indian, Akron, Ohio, Aug. 1. Time, 2:14 3-5.

Two Miles, Sidecar—Won by Jiggs Price, Harley-Davidson, Readville, Mass., Oct. 23. Time, 1:49 1-5.

Five Miles, 61—Won by Gene Walker, Indian, Readville, Mass., Oct. 23. Time, 3:50 4-5.

Five Miles, 30:50—Won by Albert Burns, Indian, Grand Junction, Colo., June 6. Time, 6:02.

Five Miles, Sidecar—Won by Floyd Clymer, Indian, Colorado, July 25. Time, 5:01.

Ten Miles, 61—Won by Ralph Hepburn, Harley-Davidson, Readville, Mass., Oct. 23. Time, 8:03 2-5.

Ten Miles, 30:50—Won by Gene Walker, Indian, Greeley, Colo., May 3. Time, 11:25.

Ten Miles, Sidecar—Won by S. J. Riddle, Indian, Pottstown, Pa., May 3. Time, 10:54.

Twenty-five Miles, 61—Won by Albert Burns, Indian, Ascot, Los Angeles, Cal., Jan. 11. Time, 18:32.

Twenty-five Miles, 30:50—Won by Don Marks, Indian, South Bend, Ind., July 1. Time, 27:00 4-5.

Twenty-five Miles, Sidecar—Won by F. R. Dreyer, Indian, Philadelphia, Pa., June 19. Time, 25:34.

Twenty-five Mile Road Race—Won by Leonard Buckner, Indian, Savannah, Ga., April 26. Time, 40:01.

Fifty Mile Road Race—Won by Gene Walker, Indian, Savannah, Ga., April 26. Time, 40:01.

Two Hundred Mile Road Race—Won by Ray Weishaar, Harley-Davidson, Marion, Ind., Sept. 6. Time 2:48:37:12.

Three Hundred Miles, 61—Won by Jim Davis, Harley-Davidson, Dodge City, Kan., July 5. Time, 3:40:04 4-5.

Water cooled engine—80. **Cylinder Arrangement:** V—Vertical; Ve—Vee; H—Horizontal; I—Inclined. **Engine Bearings:** P—Plain; B—Ball; R—Roller. **Engine Lubrication System:** Sp—Splash; C-S—Circulating Splash; F—Oil mixed with fuel; H-S—Hollow Shaft; F-F—Forced Feed. **Clutch Control:** H—Hand; F—Foot. **Type of Transmission:** Ch—Chain; B—Belt; *—Chain & Belt Optional. **Foot Boards or Footrest:** B—Foot Boards; R—Foot Rests; O—Optional; P—Pedals.

Summary of British Motorcycle Specifications

By M. W. Bourdon

See table on page 374

Number of Cylinders

Four ....1 only
Three ....1 only
Remainder:
1-cylinder .....57 per cent
*2-cylinder .....43 per cent

*25 per cent horizontally opposed.

Engine Type

Four-cycle ....80 per cent
Two-cycle ....20 per cent
Up to 2¾ hp.:
Four-cycle .....55 per cent
Two cycle ......45 per cent

Cylinder Heads

Integral ....76 per cent
Detachable ....24 per cent

Valve Location

Side ....68 per cent
Valveless ....20 per cent
Both overhead.... 6 per cent
Inlet overhead.... 6 per cent

Crankshaft Bearings

Plain ....45 per cent
Ball ....36 per cent
Roller ....13 per cent
Ball and plain.... 6 per cent

Big-End Bearings

Plain ....61 per cent
Roller ....36 per cent
Ball .... 3 per cent

Piston Material

Cast iron ....98 per cent
Aluminum .... 2 per cent

Number of Rings

Three ....65 per cent
Two ....35 per cent

Wrist Pin

Fixed in piston...81 per cent
Fixed in rod......15 per cent
Floating .... 4 per cent

Lubrication

Splash ....73 per cent
Circulating splash.20 per cent
With fuel......... 5 per cent
Forced .... 2 per cent

Clutches

Plate ....95 per cent
Miscellaneous .... 5 per cent

Clutch Control

Hand ....86 per cent
Foot ....14 per cent

Number of Gear Changes

1-speed .... 7 per cent
2-speeds ....32 per cent
3-speeds ....54 per cent
Variable belt pulley 7 per cent

Gearset Mounting

Separate ....91 per cent
Unit with engine.. 9 per cent

Transmission

Chain and belt ...48 per cent
Chain ....40 per cent
Belt only ....12 per cent

Summary of British Motorcycle Specifications

(*Continued from page 376*)

Frames

Rear rigid ....90 per cent
Rear sprung .....10 per cent

Wheels

*Non-interchangeable ....85 per cent
Interchangeable ..15 per cent
(*15 per cent have knock-out rear spindles.)

Front Brakes

Rim ....76 per cent
V rim ....18 per cent.
Expanding, drum. 4 per cent
Contracting, drum 2 per cent

Rear Brakes

Belt rim ....56 per cent
Expanding, drum..25 per cent
Special V rim.....14 per cent
Contracting, drum. 5 per cent

Motorcycle Wheel Materials

The present S.A.E. Recommended Practice for Motorcycle Spokes and Nipples, specifies a steel slightly different from that of S.A.E. Steel No. 1045.

	Present Specified Composition	S. A. E. Steel No. 1045
% Carbon	0.40 to 0.55	0.40 to 0.50
% Manganese, min.	0.50	0.50 to 0.80
% Phosphorus, max.	0.05	0.045
% Sulphur, max.	0.05	0.05

In order to have the specification conform to the standard steel the present recommended practice has been revised to specify S.A.E. Steel No. 1045.

(23) Motorcycle Wheels and Rims

The present S.A.E. Recommended Practice for Motorcycle Wheels and Rims, specifies a steel composition for rims which is very nearly the same as and no more satisfactory than S.A.E. Steel No. 1010, hence present practice is revised to specify No. 1010.

	Present Specified Composition	S.A.E. Steel No. 1010
% Carbon	0.10 to 0.15	0.05 to 0.15
% Manganese,	0.40 to 0.60	0.30 to 0.60
% Phosphorus, max.	0.05	0.045
% Sulphur, max.	0.05	0.05

ABBREVIATIONS: H-D—Heavy Duty; **†**—Semi-High Speed, Heavy Duty; **‡**—Outboard; **Mag**—Magneto; **J. S.**—Jump-Spark; **Be & Bo**—Berling or Bosch; **Eismn**—Eisemann; **B or M**—Battery or Magneto; **G**—Gasoline; **K**—Kerosene; **D**—Distillate; **S-D**—Semi-Diesel; **At-K**—Atwater-Kent.

In revolutions per minute column when there is more than one figure given—as for instance 7-900—it indicates that the R.P.M. range is 700 to 900. In each case the first number represents hundreds.

ABBREVIATIONS: **H-D**—Heavy Duty; **†**—Semi-High Speed, Heavy Duty; **‡**—Outboard; **Mag**—Magneto; **J-S**—Jump-Spark; **Be & Bo**—Berling or Bosch; **Eismn**—Eisemann; **B or M**—Battery or Magneto; **G**—Gasoline; **K**—Kerosene; **D**—Distillate; **S-D**—Semi-Diesel; **At-K**—Atwater-Kent.

In revolutions per minute column when there is more than one figure given—as for instance 7-900—it indicates that the R.P.M. range is 700 to 900. In each case the first number represents hundreds.

ABBREVIATIONS: H-D—Heavy Duty; †—Semi-High Speed, Heavy Duty; ‡—Outboard; **Mag**—Magneto; **J. S.**—Jump-Spark; **Be & Bo**—Berling or Bosch; **Eismn**—Eisemann; **B or M**—Battery or Magneto; **G**—Gasoline; **K**—Kerosene; **D**—Distillate; **S-D**—Semi-Diesel; **At-K**—Atwater-Kent.

In revolutions per minute column when there is more than one figure given—as for instance 7-900—it indicates that the R.P.M. range is 700 to 900. In each case the first number represents hundreds.

British Marine Engine Practice

By M. W. Bourdon

THERE is a tendency on the part of British manufacturers of marine motors to specialize on a more limited range of models with differing bores and strokes than was the case before the war. Nevertheless, there are still several firms who do not specialize on any particular type or types but are prepared, it would appear, to vary the leading dimensions and details, to suit even purchasers of single engines.

The fact is, the output of the average British marine motor plant is so small that very little is done or attempted in the way of standardization. All makers, of course, have stock models, but most of them require but very little persuasion to induce them to vary these in accordance with purchasers' ideas or requirements.

It will be inferred from the foregoing that the British marine engine is often a "hand-made" proposition, and, as might be surmised, no endeavor is made to turn out a low-priced product. Most of the engines can be looked upon as fairly high-class jobs, which, while making no great pretense in the way of volumetric efficiency, are built and finished with reliability and durability foremost in consideration.

There are very few attempts to follow closely along lines adopted by car engine builders, and speeds above 1000 r.p.m. are the exception. No determined effort is apparent, except in isolated cases, to take advantage of the possibilities offered by adopting a higher rate of crankshaft revolution coupled with reducing gear between engine and propeller.

Thorneycroft has a model running normally at 1400 r.p.m. and intended to be used with a propeller turning at 350 r.p.m., and it is claimed for this that the increased propeller efficiency more than compensates for the transmission loss in the reduction gear.

Until a few years back the majority of British marine engines had T head cylinders, but these are now few and far between, the great majority having L heads. There are a few examples of overhead inlets with side exhausts, but both valves overhead appear only in the designs of two makers.

Only three firms supply two stroke engines, one of these being the makers of the original engine of the type, namely Day. This make has the largest two-stroke marine motor burning gasoline or kerosene on the British market, a two cylinder 4¾ x 5 in.

The majority of engines are designed for kerosene, but very little advance has occurred of late years in the method of vaporizing this fuel, the usual plan being to adopt a large heating chamber built up or cast with a portion of the exhaust manifold. Except in the smaller sizes it is becoming less frequent to find provision for starting on gasoline and switching over to kerosene, a more usual

Marine Engine Ex

plan being to provide an opening in the heating chamber, normally covered with a flange plate, and through which the flame from a blow lamp can be made to provide the initial heating for starting from cold on kerosene.

Magneto ignition is universal, the battery type only occurring in a few cases as a supplementary ignition system.

In regard to lubrication, it is almost impossible to classify the various systems adopted. The hollow shaft system is increasing in favor, but despite this there are many firms still depending entirely upon drip feed and splash. The circulating splash system frequently includes direct leads to the main crankshaft journals, while in one type the flywheel is made use of to lift the oil from the sump to gutters carrying it to troughs under the big-ends and to others over the journals.

The conditions under which marine motors are operated, and the advisability of designing them so that they can be almost completely dismantled without disturbing the base, has induced British manufacturers to arrange subsidiary details and drives, for example, oil and water pumps, exterior to and separate from the crankcase. There is no doubt that in this connection careful consideration has been given to convenience in upkeep rather than to neatness in appearance; the majority of engines have large flange-covered hand-holes in the crankcase through which the big-ends can be reached and the pistons and connecting rods withdrawn.

It will be surmised from the foregoing that the submerged type of oil pump is quite exceptional, this unit being generally arranged well above the crankshaft axis and driven either by chain from the crankshaft or from an extension of the camshaft. Oil filtration is usually thorough, and the system provides means of readily removing filters for cleaning purposes without draining off the main supply of oil.

In circulating oil systems, the lubricant is usually cooled by carrying a water pipe through the crankcase sump in the run from the water inlet to the pump. Some makers go so far as to give this pipe several coils in its passage through the oil, so as to expose a large cooling area to the lubricant.

In one of the Brooke series, the oil in course of circulation is passed through a jacket of the induction manifold, thus serving a double purpose—cooling the oil and assisting vaporisation.

In regard to crankcase and cylinder construction, the detachable head is very rarely seen, the cylinders usually being cast separately or in pairs, and being integral units of cast iron bolted to the top of the cast iron crankcase. In most designs the latter is divided transversely in the longitudinal center line of the crankshaft, but in one or two cases the crankchamber is cast as a unit, the crankshaft being assembled through a large hole at the rear end and supported at that point by a detachable endplate which forms the bearing housing.

Non-Ferrous Metal Specifications

(*Continued from page 329*)

Specification No. 67, Semi-Plastic Bronze

Composition in percentage:

Copper	75.50 to 78.50
Tin	7.25 to 8.75
Lead	13.50 to 16.50
Zinc, max.	0.50
Phosphorus, max.	0.25
Iron, max.	0.25
Antimony, max.	0.50
Aluminum	None
Impurities, max.	0.75

General Information

Good castings made of this alloy should give the following minima in physical characteristics:

Ultimate strength, lb. per sq. in.	20,000
Elongation in 2 in. or proportionate length, per cent	10

This metal is intended for use where a soft bronze with good anti-friction qualities is desired.

Storage Battery Specifications

(Excerpts from the Report of the S.A.E. Standards Committee)

Ratings—Batteries for combined starting and lighting service shall have two ratings. The first rating shall indicate the lighting ability and shall be the capacity in ampere-hours when the battery is discharged continuously at the 5-hr. rate to a final voltage of not less than 1.7 per cell, the temperature of the battery beginning such discharge being 80 deg. fahr. The second rating shall indicate the starting ability and shall be the capacity in ampere-hours when the battery is discharged continuously at the 20-min. rate to a final voltage of not less than 1.5 per cell, the temperature of the battery beginning such discharge being 80 deg. fahr.

Terminal Posts.—When taper posts are used for terminals of lead-acid storage batteries, the dimensions in inches shall be

Small diameter of the negative post	5/8
Small diameter of the positive post	11/16
Taper per foot	1-1/3
Minimum length of taper	11/16

When straight terminal posts are used, the diameter of both the positive and negative posts shall be 13/16 in. and the minimum clear length of the post shall be 13/16 in.

These dimensions refer to batteries for lighting service as well as for combined starting and lighting service.

Compartments.—Compartments for starting and lighting batteries shall be of metal not less than 18 United States plate gage (0.050 in.) in thickness, supported entirely by the chassis.

Battery compartments shall be 8 in. wide and 10½ in. high in order to give a ¼-in. clearance all around the battery. End-to-end assembly of jars is not recommended on account of the inherent weakness of this type of construction.

The battery shall rest on two wooden strips each 2 in. wide by ¼-in. thick, running lengthwise of the compartment. **These shall be positively spaced with the edges** flush with the sides of the battery. Spacers **shall be provided to give a ¼-in. space at** each side of the battery and a 1½-in. space at each end outside of the hold-down devices.

The compartment shall be drained and ventilated.

The hold-down devices should be attached at the level of the top of the battery, not to the top of the handles.

Recommended Practice in Testing Spark Plugs

(Excerpts from the report of the S. A. E. Standards Committee)

A sufficient number of sample spark-plugs drawn at random from stock are to be fur-

Recommended Practice in Testing Spark Plugs

(*Continued from page* 384)

nished to equip at least two of the engines under consideration.

The spark-plugs submitted for test must conform in all important dimensions to the engine builder's drawings.

Preignition and leakage tests are to be made in the following manner: An engine of the type for which the plugs are intended shall be equipped with a set of the spark-plugs to be tested. The spark-plug gaps shall be carefully adjusted with a suitable thickness gage to the desired dimension and these gaps shall not be disturbed throughout the tests. The engine shall then be coupled to a suitable dynamometer and the circulating water maintained at a temperature of not less than 40 deg. fahr. or more than 60 deg fahr. The engine shall then be started up and as rapidly as possible brought to the speed corresponding to the maximum torque, the throttle and the spark adjusted for this condition, and the circulating water temperature brought up to a temperature of not less than 190 deg. fahr. nor more than 210 deg. fahr. as rapidly as possible and this temperature maintained for the remainder of the run. Torque and speed readings shall then be taken at 30-sec. intervals for a period of 15 min. Appreciable loss of torque or speed, missing or backfiring which can be attributed to the spark-plugs, will be considered grounds for rejecting the spark-plugs under test, provided the engine is of proved design and has previously demonstrated its ability to run steadily under these conditions. During this run tests for gas leakage shall be made by covering all joints of the spark-plugs with oil and inspecting for leaks.

Following this 15-min. run at the speed corresponding to maximum torque, the engine shall be brought up to the speed corresponding to maximum horsepower and be held at this speed for not less than 5 min. Observations similar to those mentioned above are to be made during this run.

Spark-plugs shall also be subjected to road tests to determine how well they will function under normal service conditions.

Spark-plugs which have successfully passed the above tests will be considered satisfactory for use in so far as the following points are concerned:

(1) Breakage owing to sudden temperature changes.
(2) Liability to cause preignition.
(3) Leakage.
(4) Power performance.
(5) Permanence of gap.

The following procedure for determining the relative susceptibility of the spark-plugs under test to fouling is intended to serve merely as a guide in making such tests, since general engine influences and more particularly lubrication and carburetion conditions varying as they do in different makes of engine, prohibit the setting of one strictly standard method applicable to all engines.

The engine equipped with the spark-plugs under test shall be run on the dynamometer with the circulating water at not less than 40 deg. fahr. nor more than 60 deg. fahr. The inlet manifold shall be kept at as low a temperature as practicable, all heating means being disconnected so far as possible. The engine shall be run with no load and a wide-open throttle, the speed being held down to between 1000 and 1500 r.p.m. by causing the carbureter to feed an abnormally rich mixture. The engine shall be run in this manner for 3 min., following which the carbureter adjustment shall be restored to standard condition and the load applied to hold the engine at a speed of about 1200 r.p.m. It is assumed that the torque which is to be expected of the engine under test at this speed, has been previously determined. At the end of 2 min. running after applying the load as above explained, the percentage of standard torque which the engine is capable of developing will be considered as a figure of merit for the spark-plugs under test. For instance, if at the end of 2 min. operation under load following the "choked" run, the engine is capable of pulling its standard torque, the spark-plugs shall be considered 100 per cent satisfactory in this regard. If, however, the engine pulls but one-half its regular torque, the figure of merit will be 50. These tests should be repeated a sufficient number of times to insure a consistent average result.

*Two stroke.
†Battery in addition to magneto; all engines have magnetos.
††Typical of range of 30 engines with 1 to 6 cylinders of 5 H.P. to 220 H.P.

ABBREVIATIONS: **Circ**—Circulating; **Comp**—Compressed; **Eccen**—Eccentric; **Elec**—Electric; **F**—Exhaust Valve Over Inlet in Pocket; **Gas**—Gasoline; †Complete Installation; **Hc**—Hand-crank; **I**—In Head; **Ker**—Kerosene; **L**—Side by Side (in L head); **Opt**—Optional; **Pist**—Piston; **Plun**—Plunger; **Press**—Pressure; **Spl**—Splash; **T**—in pockets at Both Sides (T. head).

STOCK ENGINE ABBREVIATIONS—Explanation of abbreviations: Numbers in brackets indicate the column to which reference is made; (1) C—Car; T—Truck; Tr—Tractor. (5) B—Block; P—Pairs; S—Singly; T—Threes. (7) H—Head; R—Right; L—Left; Op—Opposite; Sl—Sleeve. (10) R—Roller; M—Mushroom; R-A—Rocker Arm. (29) I—Integral; S—Separate; Opt—Optional. (30) C-P—Centrifugal Pump; T-S—Thermo-Syphon; G-P—Gear Pump; Opt—Optional. (31) S-P—Splash-Pressure; C-S—Circulating-Splash; Pr—Pressure; C-P—Circulating Pressure. (32-35) A—Aluminum; I—Iron; S-S—Semi-Steel; P-S—Pressed Steel; B—Bronze. (46) G—Gear; C—Chain. (47) S—Silent. (48) A—Adjustable.

Passenger Cars, Trucks and Tractors

Is Cylinder Offset?	If Offset—How Much?	Intake Manifold (Separate or Integral)	Water Circulated By	Lubrication System	Material of Crankcase	Material of Lower Half of Crankcase	Material of Cylinders	Material of Pistons	R.P.M. at Which Maximum H.P. is Developed	R.P.M. at Which Maximum Torque is Developed	Is Governor Fitted?	If So—What Type?	Governed Speed	Maximum Brake H.P. of Average Product	Weight of Engine Without Ignition or Carburetor (Lb.)	Overall Width of Engine (In.)	Overall Height of Engine (In.)	Overall Length of Engine (In.)	Type of Front End Drive	If Chain—What Type?	Adjustable or Non-adjustable	Points of Engine Support	Adapted for Heavy Fuel	Is Bell Housing Provided?	If So—What Number and Type?	MAKE AND MODEL

N—Non-Adjustable. Twin city model TW crankshaft stepped; Front, 2 1/4; center, 2 11/16; rear, 2 3/8. Twin City model AE crankshaft stepped; front, 2 7/8; center, 3; rear, 3 1/8. Wisconsin model RBU crankshaft stepped; front, 2 1/4; center, 2 5/16; rear, 2 3/8. Gray-Beall crankshaft stepped; front, 2; center, 2 1/16; rear, 2 1/8. Twin City horsepower rating based on gasoline as fuel. Develops 35 on model TW and 50 on model AE when using kerosene.

1921 Road Expenditures

MORE than $600,000,000 is available for road and bridge expenditures in the United States during the year 1921. The exact figure as given out by the U. S. Department of Agriculture is $622,000,000, all of which is authorized to be spent during the coming year.

As noted in the registration article, about $98,000,000 were collected as automobile fees by the various states. Adding this to the above sum gives a total of $720,000,000 which will probably be spent upon roads in this country immediately, the money received from fees being used chiefly for maintenance and repair.

Texas will spend the greatest sum on its roads, the total figure for this state being $60,000,000. New York follows with $55,000,000, and Iowa is next with $37,000,000. The ten states that will spend the most are in order:

Texas	$60,000,000
New York	55,000,000
Iowa	37,000,000
Ohio	35,000,000
Pennsylvania	30,000,000
California	26,000,000
Illinois	20,000,000
Kansas	20,000,000
Michigan	20,000,000
Minnesota	20,000,000

The fact that Texas leads this list is of interest in considering that state as a market for motor vehicles. Since it is one of the largest states as to population a large road expenditure might be expected. Nevertheless it is interesting to note that it does not yet have as many cars per capita as do several other large population states. The number of persons per car, for instance, in some of the big states is as follows:

California	6.04
Michigan	8.91
Ohio	9.34
Texas	9.79

Each of these big states which have more cars per capita than Texas, are more restricted in area. Michigan and Ohio, particularly are big manufacturing centers. In other words, Texas would seem to have certain natural advantages as an automobile market in the way of area that are not possessed by some of the other states which now lead it in cars per capita. Consequently, the expenditure of this large sum on new roads, would indicate that within the next few years the active market for cars in that state should increase materially.

The table shows that every state has made some appropriation for roads, the smallest appropriation being by the smallest state in the union, Rhode Island. The group of agricultural states has available the largest total, chiefly because it includes two of the three leaders, Texas and Iowa. The agricultural group has appropriated $201,000,000.

The manufacturing group includes Massachusetts, New York, Ohio, Pennsylvania, Michigan, Indiana, Delaware, Connecticut, Rhode Island, New Jersey and Wisconsin. The agricultural group includes Arkansas, North Dakota, South Dakota, Kansas, Minnesota, Nebraska, Oregon, Oklahoma, Texas, Washington, Iowa. The mining group includes Wyoming, Nevada, Utah, New Mexico, Montana, Colorado, Arizona, and Idaho. The Southern group includes Florida, Georgia, Virginia, North Carolina, South Carolina, West Virginia, Kentucky, Tennessee,

Louisiana, Mississippi, Alabama. The amounts appropriated by these respective groups are as follows:

Agricultural	$201,000,000
Manufacturing	171,200,000
Southern	92,500,000
Mining	44,500,000

These figures show that road building activity is to be greatest in the agricultural states during the next year, even in proportion to population since the manufacturing states hold the majority of the people. This is a natural development since the manufacturing states were, of course, the first to develop good roads.

The presence of a good-sized appropriation for the South is an encouraging sign, since good roads are the chief factor still needed to make that section an excellent market for motor vehicles.

Funds Available for Road and Bridge Expenditures, 1921

Alabama	$9,000,000
Arizona	8,000,000
Arkansas	12,000,000
California	26,000,000
Colorado	7,000,000
Connecticut	8,000,000
Delaware	3,500,000
Florida	7,725,000
Georgia	10,000,000
Idaho	4,500,000
Illinois	20,000,000
Indiana	9,500,000
Iowa	37,000,000
Kansas	20,000,000
Kentucky	8,000,000
Louisiana	6,000,000
Maine	7,500,000
Maryland	4,800,000
Massachusetts	8,000,000
Michigan	20,000,000
Minnesota	20,000,000
Mississippi	11,000,000
Missouri	15,000,000
Montana	8,500,000
Nebraska	6,000,000
Nevada	3,500,000
New Hampshire	2,500,000
New Jersey	16,000,000
New Mexico	4,000,000
New York	55,000,000
North Carolina	6,500,000
North Dakota	7,000,000
Ohio	35,000,000
Oklahoma	8,000,000
Oregon	10,000,000
Pennsylvania	30,000,000
Rhode Island	1,700,000
South Carolina	6,000,000
South Dakota	7,000,000
Tennessee	10,275,000
Texas	60,000,000
Utah	6,000,000
Vermont	2,000,000
Virginia	10,000,000
Washington	14,000,000
West Virginia	8,000,000
Wisconsin	19,500,000
Wyoming	3,000,000
Total	$622,000,000

Texas also shows the largest road appropriation per capita of the large states; that is, of the states whose population is three million or more. Texas has appropriated $12.83 per capita for road expenditure during 1921 alone. California is second in this respect with an appropriation of $7.60 per capita. Following is the way the ten large population states line up as regards appropriation per capita:

Texas	$12.83
California	7.60
Ohio	6.08
Michigan	5.45
New York	5.32
New Jersey	5.10
Missouri	4.41
Pennsylvania	3.44
Illinois	3.09
Massachusetts	2.08

An Analysis of the American Farm Lighting Plant Industry

1920 output approximately 100,000 plants valued at about $60,000,000. Seventy-five concerns manufacture about 140 models. Nearly 80 per cent are 32-volt systems. Twenty-five per cent still employ belt drive. Ninety per cent have single cylinder engines with an average of about 3 b.h.p.

By Gustave Wiedeman

THE isolated electric plant industry had in 1920 an output of about 100,000 plants valued in the neighborhood of $60,000,000. The last census shows that over two and one-half million farms still remain in this country without electrical service of any kind. At present, there are about 75 concerns manufacturing complete electric plants whose various models exceed 140.

The majority of plants are designed for general lighting and power work on small and medium sized farms. The average size of all models is 1.9 kw. Many of the units are purposely over-powered for auxiliary belt work.

Types.—The four classes or types of electric plants are: First, the 110-volt system, which employs no battery at all. It has practically disappeared. Second, the 110-volt system, using a small automobile type battery for starting purposes only. Three per cent of all models are of this class. Third, the 110-volt system (or 55 volts, optionally) having a full battery complement of 56 cells, constituting about 15 per cent of all models. Fourth, the 32-volt systems, having a full battery of 16 cells. About 80 per cent of all models fall in this class.

Thirty per cent of present electric plants are provided with auxiliary pulleys for a power take-off. These have surplus power so that belt work can be done while the plant is charging the battery. The ratio of engine power to generator output averages 3 to 1 where a power take-off is supplied and 2 to 1 where the engine drives only the generator.

Drive.—The belted plant was the pioneer in the electric plant field and to-day about 25 per cent of the models have belt drive. Six per cent of the plants have either gear or silent chain drive, which permit of efficient engine and generator speeds. This is usually an engine speed of about 1000 r.p.m. and generator speed of 2000 r.p.m. The remaining plants are all direct coupled.

Classification.—There are three kinds of electric plants, commonly referred to by the trade as (a) full automatic, (b) semi-automatic and (c) manually started. The full automatic plant starts and stops itself automatically during the line or battery charging period. In the case of 110-volt systems employing only a starting battery, a starting switch or the act of switching on the first light automatically starts up such a plant. The semi-automatic must be started by depressing a starting switch but is capable of shutting itself down when the battery is charged. The manual systems must be started and stopped and (usually) controlled by hand. This is the simplest plant of all and is most generally found in the smallest and the largest units, the intermediate sizes being of the other two kinds.

Regulation.—The life of the battery and the effectiveness of the plant depend largely upon the system of charge regulation. Charging regulation not only affects battery upkeep, conceded to be the most important item in electric plant maintenance, but also influences the operation of lamps whereby the satisfaction of a plant is measured.

The centrifugal governor is quite commonly used to hold the engine speed constant under all conditions or to restrict excessive speed by shutting off either fuel or air. A compound wound generator is best suited to this class of plants. The third system of regulation permits of varying engine speeds so as to produce a constant generator voltage. A solenoid, shunted across the generator terminals, actuates the throttle directly and produces a "tapered" charge, regardless of generator characteristics. Inherent speed regulation is occasionally used on the small units. Maximum engine speed is limited by manifold restriction or similar means. The principle of armature reaction is used in some cases to regulate plant charging.

Charge Control.—In the design of semi and full automatic plants, some principle must be selected which automatically determines the state of charge of the battery. Three such principles are in use, (a) the ampere-hour meter, (b) the voltage relay and (c) the specific gravity relay. The first of these is by far the most popular. Initially, the plant is started with the battery charged and the meter set at "full." Subsequently, every ampere-hour is added or subtracted, depending on whether it is a charge or discharge. A stopping relay commonly set at the "full" position of the meter serves to shut down the engine when that point is reached. These meters make an allowance for a battery efficiency of 80 per cent but their manufacturers recommend that they be "put in step" with the plant once a month by making a hydrometer check on their setting. The voltage relay system (b) is merely a set of relays, shunted across the battery, which act between pre-determined voltage limits and start or stop the plant charging accordingly. The specific gravity control (c) is usually worked out by employing a master cell hydrometer and using its rise and fall to actuate control relays.

Generator.—The four-pole generator appears most frequently, especially where the shunt winding is used for both generating and starting. Laminated fields are the rule. The shunt is the most popularly used field winding. The compound winding appears most fre-

quently with its series winding used for starting only although there are many generators where the series winding is employed for bucking or compensating regulation. The duplex winding is confined to the 110-volt system that uses only a starting battery, where a shunt is normally used for generating and a 12- or 24-volt winding for cranking only.

Whenever possible, designers have used generator characteristics for charge regulation, sometimes alone and more frequently in combination with some engine characteristic.

Safety or protective devices are used on all plants. Fuses appear usually on the simplest plants. The magnetic circuit-breaker is increasing in popularity for

the semi-automatic plant. Reverse current relays are a necessity with semi and full automatic plants, to protect the generator and battery against damage in case the engine stops.

Control Panels.—The manually controlled plants have rather elaborate control boards, consisting of ammeter, voltmeter, rheostat, switches, etc. Semi-automatic plants have, as a rule, the simplest control boards, consisting of a ampere-hour meter and a pair of controlling switches. The full automatic plants are made "fool proof" by concealing their control panel or compartment,

Pneumatic Equipment and Heavy Trucks

PROBABLY no question in the truck field has caused more discussion during recent years than that of pneumatic tire equipment.

Partially complete returns from a recent survey made by AUTOMOTIVE INDUSTRIES indicate a rather general unanimity of opinion on this question among truck manufacturers. Most manufacturers feel, in a general way, that the 3½-ton truck is the largest that can economically be equipped with pneumatic tires, although some believe that pneumatic equipment is not efficient on trucks larger than 2½ tons. A still smaller number think that pneumatic equipment is effective on models larger than 3½ tons.

The point was brought out, however, in a number of replies that not only the weight of the trucks but the operating purposes and conditions need to be considered when discussing the advisability of pneumatic equipment in any particular case. One manufacturer, for instance, says, " . . . We do not advocate the use of pneumatics on 3½-ton jobs unless the nature of the service has been carefully analyzed and sufficient assurance obtained that the tires would not be badly overloaded and that operating conditions are such as to enable this type of equipment to justify its higher cost . . . . We do not yet feel that trucks of this class can be indiscriminately sold on pneumatic equipment."

While a majority of those replying stated their belief that 3½-ton trucks were the largest upon which pneumatics might satisfactorily be used, some of this group was rather doubtful as to the real advisability of so equipping trucks of this size. In other words, while they felt it could be done, they are not thoroughly sold on the advisability of doing it except in special cases. One opinion ran like this: " . . . It is our opinion that pneumatic equipment reaches its limits on trucks of 2½-ton capacity, because of the fact that to withstand the hard wear and weight of the 3½-ton truck, the tires would have to be built so large that they could not be conveniently used. And furthermore, the solid tires of the large truck usually have large enough traction area, so there is no excuse for pneumatic equipment on these grounds."

Another general belief brought out by the survey was the opinion of most manufacturers that there would be a tendency towards the increased use of middle-sized trucks and a falling off in the use of the very large sizes. One manufacturer stated that, "We are firm believers in the fact that the heavy capacity truck is doomed and will be replaced with a greater number of medium capacity trucks. This we find is the condition existing all over the country, except, perhaps, in twelve or fifteen of the larger cities."

One maker thinks that the size of future trucks will be limited to the practicability of pneumatic tire sizes; that trucks will be built as large as can economically be operated on pneumatics and no larger.

Judging from the general opinions expressed as regards the attitude of the public towards pneumatic equipment for trucks of capacity of three tons and up, there is little question but that the public is rather skeptical in this regard. The following typical statements express the general opinion:

"We believe the general public in buying 3-ton sizes or over consider hard tires an investment as against the pneumatics as a speculation."

"No demand from public for pneumatic equipment on sizes of 3 tons or more."

"Attitude of public in this regard is that such equipment is not satisfactory."

While dissenting opinions are to be noted from all of the general trends indicated, a majority of truck manufacturers seem to believe in a general way the points outlined above in regard to the use of pneumatic equipment on trucks.

Billion Dollar Mark Passed in Automotive Exports

A study of the figures compiled since 1907 indicates a steady growth. Many interesting changes shown in the trend of trade since the war. Last year's total, $382,676,437, covering practically all countries.

By George E. Quisenberry*

THE foreign trade of the United States in passenger cars, trucks, motorcycles, parts, gas tractor engines and tires reached the huge total of $382,676,437 in 1920, an increase of slightly more than $175,000,000 over the preceding year. By expanding its overseas business by so great a value, the industry pushed its total export sales for all years well above the billion dollar mark, the statistics showing that the world has bought from the makers of this country $1,319,548,810 in these lines in all years since 1907.

All of the component automotive lines combined in rolling up the increase in 1920. Passenger car exports jumped from $73,700,527 to $165,255,921; trucks gained an approximate $11,000,000 to a 1920 total of $46,765,781; parts value rose from $42,562,186 to $85,362,093; the tire exports were $52,570,103, as against $28,924,659; engines from $20,026,172 to $21,965,959, and motorcycles grew from $6,687,346 to $10,756,580.

The detailed statistics follow.

	1919	1920	All Years
	24,481	37,662	126,313
Motorcycles	$6,687,346	$10,756,580	$30,963,518
	67,144	142,508	526,592
Passenger cars	$73,700,527	$165,255,921	$517,614,256
	15,485	29,126	115,236
Commercial vehicles	$35,424,337	$46,765,781	$271,904,722
Parts	$42,562,186	$85,362,093	$257,288,041
Gas tractor engines	$20,026,172	$21,965,959	$95,268,260
Tires	$28,924,659	$52,570,103	$149,570,013
Total value	$207,325,227	$382,676,437	$1,319,548,810

This does not include the aeronautic exports, of which the official reports reveal shipments of 65 airplanes, valued at $598,274, and airplane parts valued at $544,375. The corresponding totals in 1919 were 44 planes, worth $215,300, and parts valued at $3,249,266.

Records Inadequate

Unfortunately, the showing of car exports does not reflect the true volume of American automobiles which were placed in the overseas markets during the past year. The customs records give these at 142,508, a figure which in itself is sufficiently large to reveal something of the world demand for the automotive products of the United States but which, nevertheless, does not adequately point the way for calculations on replacements, accessories, maintenance parts, future markets, etc.

The reason is that pioneer figure in our foreign trading, Henry Ford. For several years, the Ford company has been establishing assembly branches in various centers which put together Ford cars from parts shipped from the Detroit factory. These, naturally, are not listed as either complete cars or chassis, but as parts, which take a different customs rating, and so do not show properly in the returns. But they are assembled into cars which should be considered as American products. For servicing and maintenance, they require spark plugs, for instance, of American sizes and other accessories of a similar nature, and they are in reality the product of American factories.

These assembling branches are located at Saõ Paulo, Brazil; Buenos Aires, Argentina; Manchester, England; Cadiz, Spain; Bordeaux and Copenhagen. Another factor is the shipment of Ford cars from the Canadian factory to those British possessions which have preferential tariff arrangements with that country. Ford has not announced the total assemblies of the foreign branches or the shipments from Canada on this basis, but, without doubt, they would swell materially the volume of American cars put in the foreign markets last year.

The Saõ Paulo branch, which has attained a reported production of 700 cars a month, takes care of only Southern Brazil, while the Buenos Aires plant, which has run as high as 1500 cars monthly, confines its sales entirely to the Argentine. All other countries of Latin-America are supplied with Ford cars and trucks from this country and show as complete cars or chassis in all cases. No Ford cars show for the Argentine and but part of those for Brazil, a condition which also exists in regard to the countries in Europe served from the European branches.

The maximum production at Manchester has been above 8,000 cars monthly, according to a recent statement, although early last year it ranged from 3,000 a month to 1,000 weekly. The Cadiz plant probably runs about 700 a month, whereas Bordeaux and Copenhagen have averaged much less.

Where Exports Go

With these factors in mind, as modifying the relative standings, a review of the 1920 exports of passenger cars, according to value and based on the customs reports, shows that England, India, Canada and Australia were the chief purchasers of complete cars and chassis. Following them come New Zealand, South Africa, Cuba, Sweden, Brazil, Dutch East Indies, Argentina, Spain, Uruguay, Philippine Islands and Mexico. Denmark, which had ranked seventh, and Norway, which had been twelfth in 1919, both dropped so low in 1920 that they did not come among the first fifteen buyers.

The purchases, according to number of machines, were

*Managing editor, El Automovil Americano.

somewhat different, although England and India were again the leaders, but Australia was ahead of Canada. After these leaders the relative order was South Africa, New Zealand, Cuba, Sweden, Argentina, Dutch East Indies, Uruguay, Mexico, Spain, Philippine Islands and Brazil.

Through all years, the fifteen leading countries in the purchase of American made cars have been Canada, England, Australia, Argentina, New Zealand, South Africa, Cuba, India, Mexico, Dutch East Indies, Philippine Islands, France, Uruguay, Japan, the Netherlands and Chile. The details of these statements may be gathered from the tables which are published elsewhere in this issue.

The countries in 1920 which purchased fewer cars than in the year before were Denmark, the Azores, Finland, France, Iceland, Chile, Roumania, British Honduras, Canada, Newfoundland and Labrador. The cars purchased by Brazil were less by 22 in 1920 but the value rose surprisingly from $2,580,304 to $6,761,382.

Among the smaller countries, there were some unusual gains between the two years, this being an evidence that the American made motor car is pushing itself into all corners of the world.

Some of these are shown in the following table:

	1919	1920
Portuguese Africa	18	244
Korea	11	595
French East India	37	537
Persia	4	128
Turkey	119	1010

Turning to the truck field, Brazil pushed prominently into the forefront of buyers. Ranking seventeenth in 1919, this Latin-American country was in fourth place last year, being exceeded only by England, Canada and Cuba, and leading India, Australia, Mexico, Japan, the Philippines and Peru, in the order named. The Brazilian gain was more than 700 per cent, from 200 to 1540. British India, the Dutch East Indies and Peru were other countries which also made surprising gains, these being as follows:

British India	266 to	1534
Dutch East Indies	324 to	1182
Peru	207 to	900

Two bright spots among the small countries which are taking their place in the truck buying field are the Virgin Islands and the Dominican Republic. The Virgin Islands, which are now American territory, made a percentage gain far surpassing anything shown in any of the other purchasing territories. One truck was sent there in 1919; in 1920 the number was 168. The Dominican Republic also made a favorable showing, taking 213 trucks as against 48 in the preceding year.

The Truck Trade

Truck exports, the comparisons show, do not always follow the motor car, although that should logically be the pioneer wedge by which any territory is opened up for automotive equipment. But, once opened, the utilization of trucks and cars may follow different lines. Three countries, for instance, appear among the first fifteen buyers of motor trucks which are not shown in the same list for passenger cars. These are Japan, Peru and West Africa, each of which increased its takings in 1920, although the early advent of the business depression in Japan prevented that country from making the gains recorded by the other two territories. On the other side of the ledger was France, which, after leading in 1919, almost dropped out of the truck market in 1920.

On the buying of tires, a much different line-up of leading purchasers was shown, the list being led by England and followed by Cuba and the Argentine. The English takings were $4,178,548, Cuba $3,409,986 and Argentina $3,126,889. The latter country, perhaps, in this comparison shows up for the first time more nearly where it should be considered as a user of American automotive equipment. Because of the big Ford assembly plant at Buenos Aires, its absorption of passenger cars and trucks is imperfectly given in the customs reports. On tires, however, this does not follow and the breadth of the market is shown without the possibility of any modification being needed.

The Argentine, in third place, was well ahead of Canada, which was followed in turn by Sweden, Philippine Islands, France, New Zealand, Brazil, Spain, Netherlands, South Africa, Dutch East Indies, Australia and Mexico. India, which had been so high in the other comparisons, was no more than nineteenth as a tire buying country.

From a constructive standpoint, a study of these exports evidences that the entire world has become a field of sale for American automotive equipment. Even the smallest countries have been buying cars and trucks. A common statement is that, whereas North America has nine million automotive vehicles, the rest of the world has but a million, or one-ninth as many. The exactness of the estimate may be questioned, but there can be no doubts here of the magnitude of the markets now confronting the American maker and the development that may be expected in coming years.

Markets Cover Every Country

Motor car and truck use outside the continental borders of the United States has expanded to an extent that two or three years ago would scarcely have been credited as possible. The American makers have been forced into foreign trade either by intention or by chance. The main point is that they are there and must stay there. The equipment already sold must be serviced and replaced; new services are being opened, and, for all of this, the American manufacturer must keep himself in the export business.

The year 1920 has been a prolific one in the sense of experience gained and lessons learned. The makers, as a whole, are better equipped today than they were twelve months ago for upholding the obligations that foreign trade has forced upon them. But the fundamentals still remain and, although our last year's trade was far in excess of that of any previous period, there can be no slackening now. Advertising, salesmanship, promotion for good roads, careful packing, the use of foreign language literature for both sales and service, proper servicing and maintenance, all of these factors must be rigidly held in upbuilding a foreign policy that will hold the markets already gained.

ACCORDING to information furnished by the Governor-General of French Western Africa, the number of automobiles imported into Senegal in 1918 was 91 (of which 85 were American and 6 French) besides 25 American trucks. In 1919 (December excepted) there were imported 94 cars, of which 87 were American and 7 French, and in addition 31 American trucks. Practically all of the American cars were of Ford and Overland make.

As regards the preferences of the population, vehicles for the country should be light, strong and of an average of 20 hp. They should have a low center of gravity and yet have plenty of ground clearance, owing to the fact that roads have hardly been broken. For city use vehicles are preferred which are heavier, more comfortable and of an average of 12-15 hp.

Canada Has 403,111 Cars and Trucks in Use

1920 totals show 13.4 per cent increase over 1919, the actual gain being 47,678. This article analyzes the Canadian registration figures and also comprises a thorough and valuable review of the present status and future prospects of the automotive industry in Canada. Tariff wall will remain high on automotive products, except on small tractors.

By Garnett Clay Porter

CANADA'S official registration of automobiles for 1920 totals 403,111. This is an increase over the 1919 registration of 47,678 cars, or 13.4 per cent. The increase of 1919 registration over that of 1918 in the Dominion was 85,706 cars.

The 1920 increase was by no means as marked as in other years. Reasons assigned by the trade quite agree as to the cause. Increased price was not so much a factor as inability of agents to guarantee delivery on orders placed in the winter of 1919-20. In the winter of 1918-19 the demand had been enormously in excess of manufacturers' capacity. The armistice brought a flood of orders. Money was the cheapest thing in the Dominion. The agrarian interests were never so flourishing. Men from the farm were in the market for cars whose pre-war conception of luxuries was confined to a fairly serviceable single horse buggy. Others with cheap grades of cars were discarding them for the more expensive types. In other words, Canada, like the rest of the world, was reacting from the rigid economies enforced by war conditions.

Frenzy of Spending in 1919

Three dollar wheat was no longer a mere figment of an optimistic rural imagination. Thousands of orders were taken following the close of the war and deposits made, with no guaranty of delivery and with the price to be determined "at time of delivery." This was the condition in Canada generally ruling in the trade in the winter of 1918-19. Then came the abolition of the government wheat board which had handled the crop so profitably to Canadian farmers in 1918-19. This machinery was expected to operate during 1920, but Ottawa authority desired to see the old supply and demand law of commerce re-established as soon as possible. The beginning had to be made with the great basic industries. All the political influence of the vast agrarian bund of the Dominion, commonly known as the United Grain Growers, was insufficient to change the Ottawa decision.

GRAIN PRODUCTION 1920, IN BUSHELS

Saskatchewan	298,474,200
Alberta	177,475,400
Manitoba	127,895,400
Total	604,445,000

Indeed, the spending frenzy had reached such proportions that the Dominion Government imposed a luxury tax to slow down the wheels of the spending multitude. It was particularly trying, this tax, on the automobile industry. In this trade the tax was known as an excise impost and was 15 per cent on all cars under $3,000 and 20 per cent over that amount.

As an offset, the 7½ per cent war tax added to the customs duty was abolished. This helped the United States manufacturers in the Canadian market, but proved really an additional burden to the manufacturers of cars in Canada. It meant to the Canadian trade that the already high price of cars had to be increased to the buying trade at least 15 per cent. The uncertainty of the grain market slowed down the buying in rural districts. These were the conditions which handicapped the automotive industries in the Dominion in 1920. Late in the fall of last year the orders for cars to be delivered this spring were appreciably less.

But then came another reaction, due to the abolition of the luxury tax and the excise burden. Prices came down to that extent and the new year opened with business prospects good. Various representatives of the trade from coast to coast have informed the writer that during January their orders increased enormously. All predict a prosperous year for the trade in Canada, especially in the west.

Tractor Demand Increases

In the three prairie provinces there were, during 1920, 31,998 farm tractors as against 26,832 in 1919. These are not official government registration figures, as the provinces do not require owners of farm tractors to register them. There were compiled from records of the grain growers, agricultural societies and customs offices.

OFFICIAL REGISTRATION OF AUTOMOBILES IN CANADA FOR TEN YEARS

TOTAL FOR 1920, 403,111, INCREASE OVER 1919, 13.4 PER CENT

Year	Ont.	Sask.	Que.	Alta.	Man.	B. C.	N. S.	N. B.	P. E. I.	Total
1911	11,339	1,304	1,878	1,631	2,599	2,220	228	483	...	21,682
1912	16,266	2,268	3,535	2,505	4,770	4,289	456	700	...	34,789
1913	23,700	4,659	5,452	3,773	5,406	6,138	511	824	26	50,489
1914	31,724	8,027	7,413	4,728	7,001	6,688	544	1,260	30	67,415

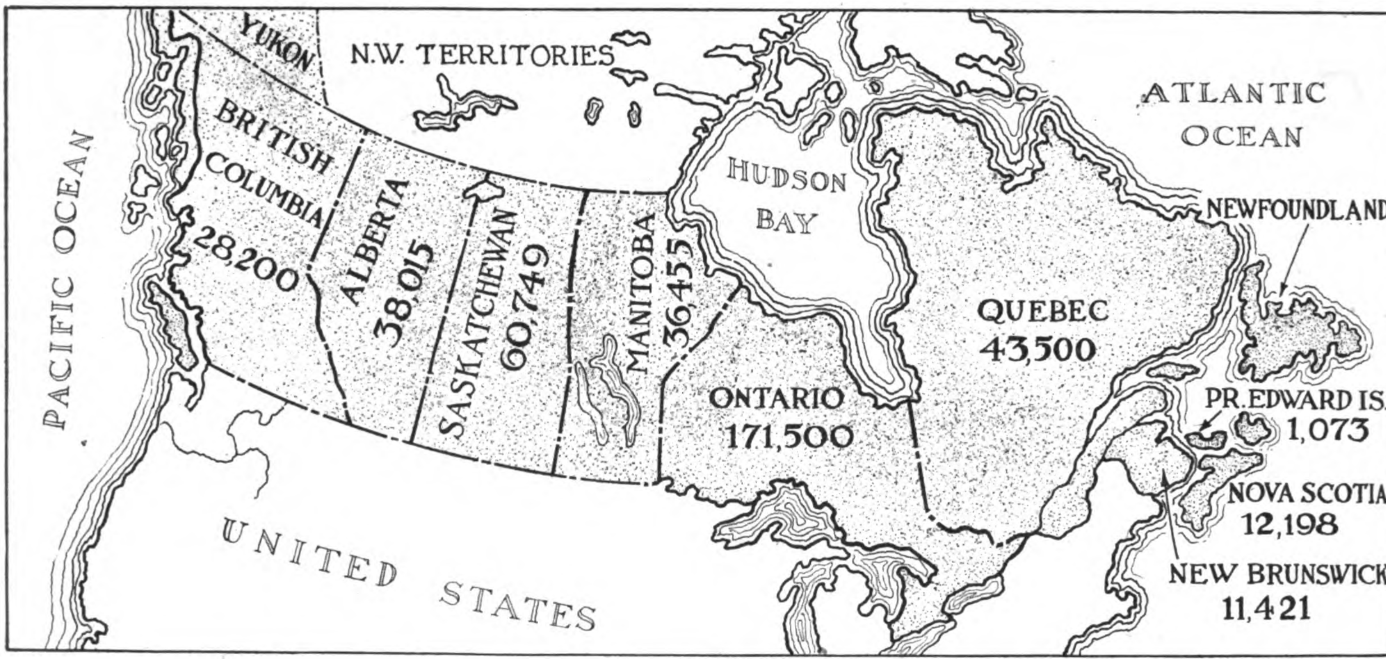
1916	54,375	15,000	15,347	9,703	11,953	8,576	1,728	2,986	50	120,318
1917	83,790	32,500	21,702	20,800	17,333	11,386	5,678	5,249	301	198,739
1918	109,374	47,239	28,388	29,500	24,389	15,828	8,103	6,475	481	269,727
1919	151,623	54,754	40,557	34,362	33,896	19,050	10,981	9,420	790	355,433
1920	171,500	60,749	43,500	38,015	36,455	28,200	12,198	11,421	1,073	403,111



Motor vehicle registration in various Canadian provinces

Tractor Record on Prairies for Four Years

	1917	1918	1919	1920
Saskatchewan	8,610	10,937	14,207	16,907
Alberta	3,977	5,209	7,122	8,700
Manitoba	1,613	3,631	5,503	6,391
Total	14,200	19,777	26,832	31,998

The impression is very general that 1921 will show a huge increase in the demand for tractors. The Federal Government has placed some 30,000 ex-service men on farms in the west. Many of them produced good crops last year. This year they will be potential buyers of farm tractors and automobiles. To appreciate the possibilities of the western Canadian farm for automotive industries it must be recalled that in 1920 there were cultivated 29,279,000 acres, and the total grain production of the three prairie provinces was 604,445,000. An increase of fully 20 per cent. is indicated for 1921, due to virgin sod being broken and the exceptional season last year for the fall plowing, which, in these northern latitudes, is always the big problem.

No Duty on Small Tractors Likely

President W. H. Gibson of the Saskatchewan Livestock Association, at the annual meeting of that organization at Moosejaw, Sask., Jan. 25, declared that prairie farmers were beginning to prefer the horse again to the tractor, and the secretary's annual address asserted that "the tendency of our farmers is to swing back from high priced tractors to really good draft horses." But the automotive trade record does not bear out this forecast, for a new factory was opened at Saskatoon, Sask., in 1920 for the manufacture of the light prairie tractor, and a similar plant was opened at Medicine Hat, Alta. In fact the abolition of the customs duty on the $1,400 tractor type proved such a lure to the United States manufacturers of tractors that the manufacturers on this side have been doing everything they could since the close of the war to have the duty reimposed. The writer was over the country with Sir Henry Drayton, Minister of Finance, sitting with other members of the Federal cabinet as a tariff commission last fall. At both Saskatoon and Medicine Hat representations were made by tractor manufacturers to have the customs duty on the $1,400 tractor re-established.

In this connection the writer thinks it important to the manufacturer of both tractors and automobiles in the United States that he emphasize this: There is little probability, in fact only the remotest, of the Dominion Government's policy concerning the tariff regulations on tractors and automotive production of every description being changed. I took special note of the attitude of Sir Henry Drayton, chairman of the Tariff Commission, during the session at Medicine Hat last fall, when the manager of the new plant producing farm tractors there submitted his brief urging a resumption of the tariff on the small type of tractor, such as he was turning out. I recall distinctly that Sir Henry Drayton bore down on this point in interrogating the manager of the tractor manufacturing company: "But you knew when you established your plant for the manufacture of this class of tractors that your industry was not protected by the tariff?" Senator Robertson, the other member of the commission, nodded his head as if in agreement with the idea brought out by the chairman.

Municipal Distribution of Cars, 1920; Rural Excess, 119,145

	Cities	Village, Town, Townships
Ontario	63,478	108,022
Saskatchewan	18,213	42,436
Quebec	13,791	29,709
Alberta	11,341	26,674
Manitoba	14,322	22,133
British Columbia	12,377	15,823
Nova Scotia	4,121	8,077
New Brunswick	3,988	7,433
Prince Edward Island	352	721
Total	141,983	261,128

The commission, of course, has been investigating industrial conditions all over the Dominion with a view of submitting facts as the members find them. Their personal views will not prevail, but the policy of the Meighen Federal Government is strongly one of protective tariff generally, but with a tendency to treat the implements of production rather from the farmers' point of view. The Meighen government has a majority in Parliament at present of thirty. The next Federal election will occur in the late spring of 1922. It can be safely predicted that no resumption of the duty on $1,400 tractors will be made by this government, nor will there be any

reduction in that time of the duty on automobiles.

The duty on small tractors was removed as a war time measure to increase production. It has worked so well and proven so popular that in spite of the manufacturers of this type of tractors in Canada there is little probability of the duty ever being re-established.

The political complexion of the next government is in doubt. The country is rather evenly divided between the National Liberal and Conservative party now in power at Ottawa, the Farmers, and the Liberals. The Meighen government is openly pledged to a protective tariff policy. The Liberal strength is chiefly in Quebec, and that French province is largely a protective tariff section, though the Liberal platform calls for "such changes in the tariff as the needs of industry may require," while the farmers rather are inclined to free trade, in farm implements at least.

With the basis of political calculations vastly disturbed in Canada, it is still a pretty safe prediction that the elements opposed to any considerable change in present tariff relations will control the destinies of the Dominion for at least five years after the next election. The attitude of the Washington authorities in placing an embargo, or advocating such an embargo, on wheat and cattle, which Canada sends so heavily into the States, has strengthened the element on this side which is opposed in principle to reducing the customs wall. So automobile manufacturers in the States may make up their minds that they will continue to climb the tariff wall to get into Canada, and those manufacturing the small type of tractor may rest assured that there is unlikely to be a duty reimposed on their products coming over the line to the northward.

Canadian Oil Industry

In this connection, those interested in the oil and gasoline industry should study the situation now developing on this side of the line, for it is certain to loom large on the horizon of the trade before the close of the year. The Imperial Oil Co. of Canada, which is the Canadian name for the Standard, has definitely located a new oil field in the Mackenzie River basin at a point some 1000 to 1500 miles north of rail head in the Northwest Territories. Two wells have been drilled and one is unquestionably a gusher, flowing, on the best evidence that has come up from the Arctic, 1500 barrels daily. The importance of the discovery is suggested by the suspension of all regulations by the Dominion Government of oil and mineral land leases.

Energetic efforts are being made to get the Mackenzie River products onto the market. It is freely predicted that this petroleum will be a factor in the world market by this fall. A railroad is projected over the 16-mile portage which obstructs the all-water route via the Mackenzie River, Great Slave Lake, the Peace River and their tributaries to the rail head at Peace River Crossing, Alberta. There are indications that tank steamers will operate on both sides of this short portage, across which a pipe line will be constructed, to rail head. That public sentiment will permit these products to go out of the country in their raw state is quite remote. The probabilities are that all refining will be forced on the Canadian side of the line.

Large Potential Market for Automotive Products

But this means an era of cheaper gasoline and oil in Canada if not in the States. This is one of the imponderable factors in estimating the possible potentiality of the Canadian market for the automotive industry in the future. The trade estimates that each car will use annually 275 gallons of gasoline, at 40 cents, giving a total money value of the quantity at $44,342,210 for 1921, or 110,895,525 gallons. Each of these cars will use four tires in 1921, or 1,612,444 at estimated value of $40,321,-100. Each car will use for grease one-tenth of the value of gasoline consumed, estimated at $4,434,221, and it is estimated that 10 per cent of the value of a car is consumed each year in accessories, giving a possible expenditure for 1921 in Canada of $80,622,200, or a total expenditure for the cars as per registration this year in Canada of $169,719,731.

POTENTIAL BUSINESS FOR 1921 IN CANADIAN AUTOMOBILE INDUSTRY, BASED ON 1920 RECORDS

Each car will use four tires, 1,612,444; probable total value	$40,321,100
Each car consumes 275 gallons gasoline, 110,-895,525 gallons, value	44,342,210
Ten per cent value, all cars spent annually in accessories	80,622,200
Cars will use one-tenth value of gasoline in grease and oil	4,434,221
Total probable expenditures of cars in service 1921	$169,719,731

It is worth noting in considering these registration figures that some members of the trade deduct 5 per cent from all registrations for duplications. Undoubtedly this uncertain quantity accounts for some disputes in totals. When a car is sold to another user, he applies for a license. These duplications are weeded out at some of the capitals better than in others, but the feature is worth noting.

The registration shows 355,550 cars registered as passenger cars and 47,561 as commercial cars; but E. M. Trowern of Ottawa, who presented the brief before Sir Henry Drayton at Ottawa in December, when a plea was being made for the remission of the excise duty on cars on which the tax had been paid before it was abolished last fall, estimated that "about 85 per cent of all the cars sold in Canada are used for business purposes."

PASSENGER CARS, COMMERCIAL CARS AND MOTORCYCLES BY PROVINCES

December 31, 1920

	Passenger Car	Commercial Car	Motor-cycles
Ontario	155,500	16,000	5,500
Saskatchewan	51,514	9,235	3,125
Quebec	36,098	7,402	2,410
Alberta	33,094	4,921	2,040
Manitoba	31,827	4,628	3,209
British Columbia	25,056	3,144	1,611
Nova Scotia	11,098	1,100	980
New Brunswick	10,511	910	527
Prince Edward Island	852	221	....
Totals	355,550	47,561	19,535

It was from the Trowern brief that the following figures were secured. He recorded for the benefit of the Dominion of Finance Minister that: "The number of employees in the Canadian automobile factories is 20,000. There are 5,550 dealers actually merchandising cars in Canada. Allowing eight employees to each establishment gives a total of 44,000. If you allow five to a family of all these, a total is given of 320,000 direct dependents upon the automotive industries of Canada."

It is worth noting that the Government did not refund the tax on cars in stock of dealers at the time the tax was abolished, upon the theory that when the tax was imposed it did not apply to cars then in the hands of dealers. The leaders of the industry are still urging action in this direction, however. In actual operation, the failure to secure this rebate will mean that those dealers who have cars on sale on which they have paid the tax must lose same, as new cars delivered will be sold at a price proportionately less to the trade. This tax had to be paid at the time the car passed from factory to dealer.

CARS PER CAPITA ON PRAIRIES

	Population	Cars 1919	Per Cap.	Cars 1920	Per Cap.
Saskatchewan ...	647,835	54,754	11.8	60,749	10.7
Manitoba	553,860	33,806	16.8	36,455	15.6
Alberta	496,525	34,806	14.3	38,015	12.9
Total	1,698,220	122,922		135,219	

Increase over 1919 of 21,347 cars.

Prairies Form Chief Market

While Ontario and Quebec are big users of cars, the prairies continue to be the rich field for the business. For the three prairie provinces, with a population of 1,698,220, registered last year 135,219 cars as compared with 122,922 in 1919, an increase of 21,347. The four western provinces show 326 repairshops, 1117 garagemen and 1669 dealers. The estimated value of cars registered in the four western provinces for 1920 is $343,179,900 and $70,384,600 for tractors. The use of tractors and motor trucks for drawing grain to market is increasing all over the prairies. This is the testimony submitted at the annual meetings of the western grain growers, where it was said that even on bad roads 75 bushels could easily be handled by small tractors and motor trucks. In 1919 there were 89 distinct makes of cars registered in western Canada, and for 1920 the different makes had increased to 112. That these roads must improve for this traffic is indicated by increased revenue being devoted to road purposes all over Canada, $20,000,000 now being in sight for this purpose in Manitoba alone. The automobile leagues of Canada are responsible for this fine spirit, the Ontario Motor League alone increasing its membership in 1920 from 6607 to 11,115. Many agricultural societies are establishing tractor schools and the western universities are encouraging such departments.

REPAIRSHOPS, DEALERS AND GARAGEMEN IN WEST

	Shops 1919	Shops 1920	Garagemen 1919	Garagemen 1920	Retail Car Dealers 1919	Retail Car Dealers 1920
Saskatchewan	84	97	451	478	493	541
Alberta	55	63	198	214	380	394
Manitoba	95	105	284	321	415	510
British Columbia...	43	61	123	104	184	224
Total	277	326	1,056	1,117	1,472	1,669

INVESTED CAPITAL IN CARS THROUGH WEST AND POSSIBILITIES—AVERAGE PRICE IN WEST $2,100 PER CAR—AVERAGE TRACTOR $2,200 PER MACHINE

	Cars, 1920	Value	Tractors	1920 Value	Grain Acreage 1920
Sask.	60,749	$127,752,900	16,907	$37,184,400	16,270,000
Alta.	38,015	79,831,500	8,700	19,140,000	7,140,000
Man.	36,455	76,555,500	6,391	14,060,200	5,769,000
Brit. Col.	28,200	59,220,000	....	....	....
Total ..	163,419	$343,179,900	31,998	$70,384,600	29,279,000

These figures are authentic as far as they go, according to the Federal Government records at Ottawa. In many of the Canadian factories, so much of the car parts turned out complete are imported, chiefly from the States, that it is difficult to figure the extent of the purely Canadian industry and the number of cars each factory produces. The tendency, however, is for the United States factories to extend their assembly plants here and rely wholly on the factory product on this side to accommodate this growing Canadian market. There were ten automobile manufacturers registered in Canada in 1919 and eleven in 1920. One large factory is being established now at Winnipeg which is not included in this list, and there are several other old munition factories that will be equipped during 1921 for the manufacture of whole or parts of cars.

These factories turned out, in 1919, 89,900 cars, valued at $70,000,000, with 17,542 employees; while in 1920 they completed 94,421 cars, at a value of $78,000,000, and employed 20,000 persons. These values are those given for taxation purposes at the factories. In 1919 the cars and parts imported were valued at $29,768,000, and in 1920 these importations had fallen to $27,900,000. The manufacturing end of the cars for the Canadian territory is expected to increase considerably this year.

MANUFACTURERS IN CANADA AND IMPORTATIONS

	1919	Factory Value	1920	Factory Value
Total factories in Canada ..	10		11	
Number cars turned out..	89,900	$70,000,000	94,421	$78,000,000
Number employees in factories ..	17,542		20,000

Cars imported valued at ..	$29,768,000		$27,900,000	

Recent Motor Vehicle Lighting Laws in the Chief Canadian Provinces

(Latest Available Reports)

Province	Headlights	Regulations for Dimming	Spotlights and Searchlights
Alberta	Lights of moving or standing vehicles must be visible 200 ft. ahead and must display license number in figures 1 in. high.	The direct beam of light must not rise above 42 in. at a point 75 ft. ahead.	"No motor vehicle shall carry what is known to the trade as a searchlight."
British Columbia.	Efficient lights required. Lamp glass must display license number in black figures 1 in. high.	Lamp glass must be ground or painted.	No searchlights, intermittent lights or flashlights are allowed.
Manitoba	Lights must be visible 200 ft. ahead without glare.	Non-glare lens or other device is required and must be approved by the Municipal Commissioner or inspectors.	No searchlight is allowed on any motor vehicle.
New Brunswick..	Lights must be visible a reasonable distance.	Dimmers or non-glare lights are required.	No special law.
Nova Scotia	Lights visible a reasonable distance are required 1 hr. after sunset until 1 hr. before sunrise.	Lights must not dazzle.	
Ontario	Lights clearly visible 200 ft. are required.	No light over 4 cp. equipped with a reflector shall project a beam over 42 in. high at a point 75 ft. or more ahead.	Subject to laws governing headlights and dimming.
Quebec	Lights visible reasonable distance required.	Due precaution against glare must be taken.	No dazzling lights are allowed.
Saskatchewan ...	Lights must be visible 200 ft. under normal atmospheric conditions and reveal person 100 ft. ahead and 10 ft. to either side.	Lights must be permanently dimmed to prevent glare.	No special law.
Toronto	Lights must be clearly visible 200 ft.	No light of over 4 cp., equipped with a reflector, shall rise above 42 in. 75 ft. or more ahead.	No pivoted light allowed, or any light that can be projected in different directions.

The Trend of the Oil Industry in 1920

Year proves the most remarkable in history in nearly all respects. Commanding features are unusually large production, rapidly mounting imports, failure to locate quota of new pools, rapid rise of prices in first quarter and overproduction accompanied by declining prices near close.

By Joseph E. Pogue[1]

In practically all respects 1920 was the most remarkable year in the history of the petroleum industry. The commanding features of the twelve months just ended, so far as the automotive industry is concerned, were five in number: the unusually high volume attained by the domestic production of crude petroleum; the rapidly mounting imports of crude oil from Mexico; the failure of an active drilling campaign to bring in its due quota of new pools; a rapid rise of oil prices during the first quarter of the year; and the development of a period of overproduction accompanied by declining prices toward the close of the year.

Crude Petroleum.

The production of crude petroleum in the United States in 1920 attained the surprising total of 447 million barrels,[2] an advance of 18 per cent over the output of 378 million barrels characteristic of 1911. During the same period the domestic consumption of crude petroleum increased 28 per cent, from 419 million barrels in 1919 to 538 million barrels in 1920. This widening gap between production and consumption was made possible by a notable increase in imports from Mexico, which jumped from 53 million barrels in 1919 to 108 million barrels in 1920, thus slightly more than doubling. These relations are shown graphically in Fig. 1.

[1] Consulting engineer, New York.

[2] The 1920 totals given throughout this article are estimates based upon official figures for the first ten or eleven months of the year, to which are added graphically computed estimates for the remaining one or two months to complete the year. The totals given, therefore, will doubtless differ slightly from the official figures available in February or March, but the divergence will be of slight significance.

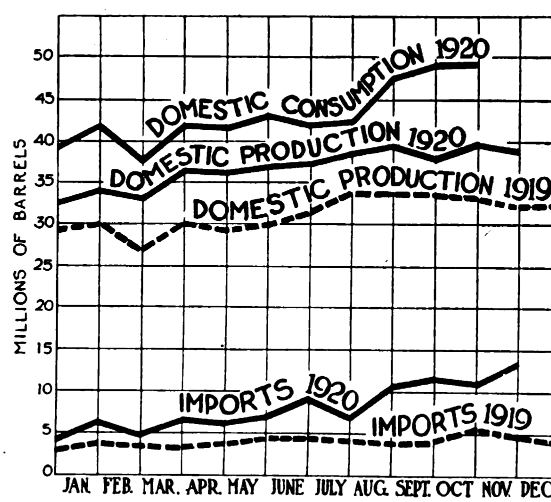

Fig. 2—Trend of the crude petroleum situation by months, 1919-1920

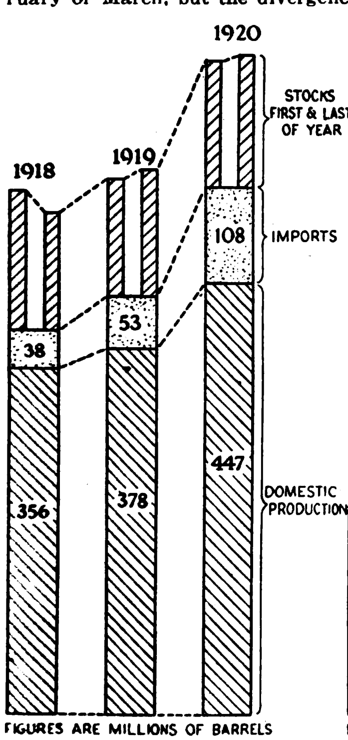

Fig. 1—Comparison of production, imports and stocks of crude petroleum in the United States, 1918, 1919, 1920

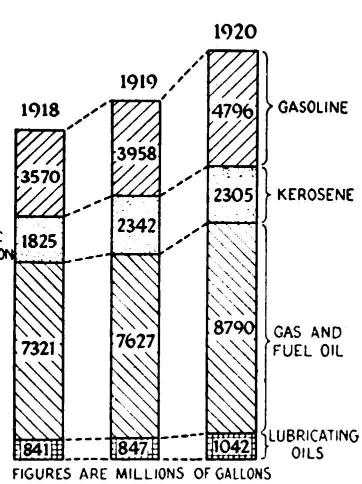

Fig. 3—Comparison of the production (of the major) petroleum products in the United States by years, 1918, 1919, 1920

Such were the year to year changes. During the course of 1920 production speeded up markedly during the first quarter of the year, maintained a good pace during the second and third quarters, and slowed up during the last quarter in reaction to conditions of overproduction that became evident toward the close of the year. Stocks of crude petroleum in the country reflected this condition by increasing from 128 million barrels on Jan. 1, 1920, to 137 million barrels on Dec. 31, 1920. During the year, imports of crude petroleum displayed an accelerating rate of increase. These relationships are presented graphically in Fig. 2.

During 1920, also, the number of oil wells brought to completion in the United States totaled 33,678, an increase of 16 per cent over the 29,069 wells completed in the year preceding. The figures just given reflect the intensity of the drilling campaign that characterized most of the year. It may be noted in this connection that on Oct. 31 there were 258,600 producing oil wells in the United States, averaging 4.98 barrels of oil each per day. The ratio of new wells to producing wells is a significant figure, pointing to the growing cost of oil production.

Between Jan. 1 and Oct. 15, 1920, the refinery capacity

of the United States, already in excess of the crude oil produced, increased approximately 27 per cent. Toward the close of the year the daily capacity of all the refineries in the country was 1946 thousand barrels, whereas the oils run daily to stills was only 1415 thousand barrels. Only about 73 per cent of the installed capacity was therefore being utilized in October, the month to which the figures just cited refer; and in November and December refinery activity notably fell off as a result of the seasonal decline superimposed upon the business depression. It is apparent, therefore, that the refineries of the United States are equipped in excess of market requirements, and many small refineries have in consequence ceased operations.

Petroleum Production

The principal petroleum products and those of interest to the automotive industry are, of course, gasoline, kerosene, fuel oil and lubricating oils. These four products, being made from the same raw material, have a joint relationship both as to quantity produced and market price. They should be looked upon in this light, therefore, if the true significance of their changes in status is to be grasped. A comparison of the production of these products in 1920 with their output in 1919 is given in Table I and graphically displayed in Fig. 3.

TABLE 1.—TREND OF PRODUCTION IN THE OIL INDUSTRY

		1918	1919	1920	Per cent change, 1918-1919	Per cent change, 1919-1920
Crude petroleum,	mill. bbl.	356	378	447	+ 6%	+18%
Gasoline,	mill. gal.	3570	3958	4796	+11%	+21%
Kerosene,	mill. gal.	1825	2342	2305	+29%	— 2%
Gas and Fuel Oil,	mill. gal.	7321	7627	8790	+ 4%	+15%
Lubricating Oils,	mill. gal.	841	847	1042	+ 1%	+23%

The last two columns of the table are particularly informing, since they unmistakably reflect the effect of the

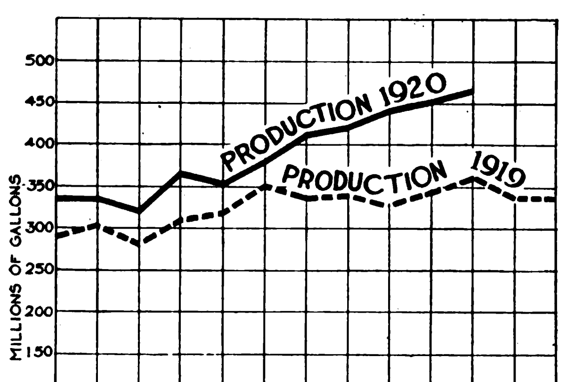

Fig. 4—Trend of the production and exports of gasoline by months, 1919-1920

automotive demand upon oil production. In 1919-1920 two products, gasoline and lubricating oil, entering into automotive transportation, increased more strongly than the domestic production of crude petroleum, whereas kerosene and fuel oil showed a smaller percentage increase than crude petroleum. With due qualification in mind, it is evident that a portion of the gasoline was made at the expense of kerosene and fuel oil, and a portion of the lubricating oils at the expense of fuel oil. This tendency, in spite of minor fluctuations and reversals, bids fair to continue with the expansion of automotive transportation.

Gasoline

The production of gasoline in the United States in 1920 attained the amazing total of 4796 million gallons, an increase of 838 million gallons over the 1919 output. The record production made in 1920 emphasizes the extent to which gasoline production was forced to meet the requirements of automotive transportation. Of the quantity produced in 1920, 618 million gallons, or 14.9 per cent, went abroad, leaving a domestic consumption of 4125 gallons, if the changes in stocks are taken into consideration. The trend of production and exports of gasoline during 1919 and 1920 is shown in Fig. 4.

The marked increase in output of gasoline, which ex-

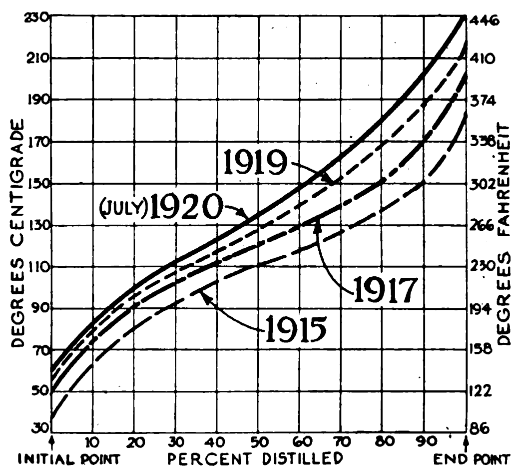

Fig. 5—Trend of the change in volatility of gasoline 1915-1920, *showing the rise in end-point. Data from U. S. Bureau of Mines*

ceeded the expectations of many of the most sanguine, was not attained without effort. A comparison with the increase in kerosene output (see Table I) suggests that an increased quantity of the light kerosene ends went into the gasoline supply to augment its volume. The degree to which the gasoline supply of the country was supplemented in this manner is shown by a country-wide motor gasoline survey conducted by the U. S. Bureau of Mines, the results of which are summarized in the following table:

TABLE 2.—TREND OF THE ENDPOINT OF MOTOR GASOLINE
Data from U. S. Bureau of Mines

	Endpoint, April, 1919	Endpoint, January, 1920	Endpoint, July, 1920
New York	411° F	418° F	432° F
Washington	426° F	439° F	449° F
Pittsburgh	425° F	425° F	454° F
Chicago	423° F	445° F	455° F
New Orleans	435° F	424° F	445° F
Salt Lake City....	441° F	440° F	456° F
San Francisco	374° F	406° F	428° F
Average	417° F	427° F	456° F

The change in the average endpoint of motor gasoline since 1915 is shown graphically in Fig. 5.

The rising endpoint of gasoline has attracted endless attention on the part of the automotive industry, although the true significance of this change has not been altogether fully understood in all quarters. The gasoline requirements of the country and of the export trade have grown so rapidly that the supply of gasoline has kept pace only by virtue of a change in volatility so as to include a greater proportion of the crude petroleum. In spite of additions to the normal gasoline supply in the form of volatile gasoline won from natural gas, and

gasoline produced from gas oil by means of cracking methods of distillation, a shortage would have intervened had a highly volatile standard been maintained. As to the future, it is probable that the endpoint of gasoline will show fluctuations and even recessions for a time, although it is the belief of many that the continued growth of automotive transportation in the years ahead will force still further changes toward a heavier and less volatile motor fuel.

Kerosene is assuming a growing interest to the automotive industry because of its use in the heavy service internal combustion engine, although the bulk of the kerosene is still used for purposes of producing light and heat. During 1920 as compared with 1919, kerosene showed a decline in both production and exports, in this respect standing in a marked contrast to the other principal petroleum products. The output of kerosene fell from 2342 million gallons in 1919 to 2305 million gallons in 1920, while the exports declined from 979 million gallons to 842 million gallons during the same period. These recessions in the quantity of kerosene coming on the market in the face of a greatly increased refinery consumption of crude petroleum merely represent a complementary circumstance to the high endpoint of gasoline.

Gas and Fuel Oil

Fuel oil, and its lighter, more highly refined variety gas oil, constituted 52 per cent of the total output of the four major petroleum products in 1920, as compared with gasoline which represented 28 per cent of the total. It is obvious, therefore, that fuel oil is a liquid fuel reserve of almost double the magnitude of gasoline, and too much emphasis cannot be laid upon the importance of this product as potential motor-fuel, whether the transition is made through cracking, changes in the automotive apparatus, or a combination of refinery and engine changes. The domestic output of gas and fuel oil increased from 7627 million gallons in 1919 to 8790 million gallons in 1920, an advance of 15 per cent. During the same period the exports of these products increased 35 per cent, or from 618 million gallons to 837 million gallons.

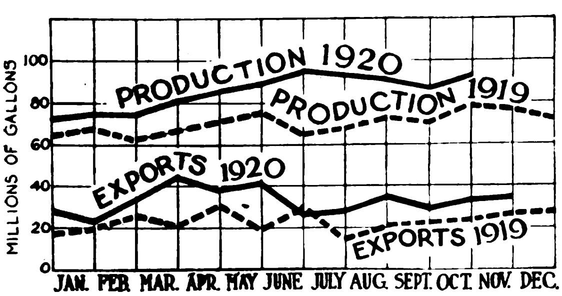

Fig. 6—Trend of the production and exports of lubricating oils by months, 1919-1920

Toward the middle of the year a serious shortage of gas oil developed, because of its growing utilization for the manufacture of cracked gasoline. Considerable attention was directed to the prospective supply by the gas companies of the country, since gas oil is widely used for enriching, or carbureting, manufactured city gas. The upshot of the wide publicity given the matter was an increased appreciation of the close interrelationship existing between the joint products of petroleum, and of the far-reaching influence upon the oil industry arising from the requirements of automotive transportation.

The production of lubricating oils in 1920 attained the surprising total of 1042 million gallons, an advance of 23 per cent over the 847 million gallons turned out in 1919. At the same time, exports increased from 275 million gallons to 401 million gallons. With the changes in stocks figured in, domestic consumption of lubricating oils increased from 574 million gallons in 1919 to 623 million gallons in 1920, the increase being largely due to the increased demand for motor oils.

The trend of the production and exports of lubricating oils during 1919 and 1920 is shown graphically in Fig. 6.

During the year considerable attention was devoted to the problem of dilution, and the relation between high endpoint gasoline and thinned out crankcase oil was clearly apprehended. This point was actively discussed at the meeting of the American Petroleum Institute in Washington in November, when the problem was looked at jointly by both automotive and oil engineers. The recognition of dilution as a part of the fuel problem registers an important step forward in the handling of this issue.

Exports

Exports of petroleum products play an important rôle influencing domestic prices, a vigorous export demand serving to take up the slack between supply and domestic demand. A comparative view of the exports of the major petroleum products in 1914, 1919 and 1920 is accordingly shown in the subjoined table, the year 1914 being introduced to indicate the pre-war export requirements.

TABLE 3.—EXPORTS OF THE PRINCIPAL PETROLEUM PRODUCTS IN 1914, 1919 AND 1920

	Exports, mill. gals.			Per cent of production exported		
	1914	1919	1920	1914	1919	1920
Gasoline	210	372	618	14	9	13
Kerosene	1010	979	842	52	42	36
Gas and Fuel Oil	703	618	837	19	8	10
Lubricating Oils	192	275	401	37	32	38

It will be observed that kerosene and lubricating oils group together in the fact that between one-third and one-half of the domestic output is normally sent abroad, whereas gasoline and fuel oil show an export factor of between one-tenth and one-fifth.

The stocks of petroleum products in storage in this country carry an important market meaning as a barometer indicating the tension between supply and demand. A detailed account of the course of stocks would be a long story, but a general view may be obtained from Table 4, in which the stocks of gasoline, kerosene, fuel oil and lubricating oils on hand on Oct. 31, 1919, and Oct. 31, 1920, are expressed in terms of the number of days' supply represented by these quantities.

TABLE 4.—NUMBER OF DAYS' SUPPLY REPRESENTED BY STOCKS ON HAND OCT. 31, 1919, AND OCT. 31, 1920[a]

	October 31, 1919	October 31, 1920
Gasoline	34 days	23 days
Kerosene	51 days	63 days
Gas and Fuel Oil	40 days	34 days
Lubricating Oils	66 days	49 days

[a]Calculated by dividing the stocks on hand by the average monthly consumption for the year.

In a period of falling prices in which accumulation of stocks of many commodities were in evidence, it is important to note the relative decline of petroleum products in storage, kerosene being the only major petroleum product showing an advance over 1919, and that but a moderate advance. Further significance of these figures appears from a comparison with the average stocks of all commodities which have been estimated by the Chase

National Bank to have been approximately 41 per cent of the annual production on Feb. 1, 1920, or roughly 150 days' supply. It is, therefore, apparent that the working reserve of petroleum products in this country is less than half as great as the working reserve of commodities in general. In spite of these conditions, the stocks of the major petroleum products have been increasing slightly during the latter portion of the year, particularly since autumn, as a result of a combination of the normal seasonal slackening in demand combined with the results of the business depression. Such changes, however, are to be looked upon as temporary fluctuations rather than fundamental alterations.

Prices

The price situation showed some interesting developments in the year just past. During the first quarter of the year the price of crude petroleum advanced sharply, rising some 40 per cent between Jan. 1 and March 31. This sharp advance was accompanied by an analogous rise in the price of fuel oil and lubricating oils, and by a less precipitate but still a notable increase in gasoline and kerosene. The second quarter of the year saw further rises in the price level, which became more or less stabilized for the rest of the year for crude petroleum, gasoline, and kerosene, but broke into sharp declines for fuel oil and lubricating oils, the two last named products tending to follow the price decline of commodities in general.

This remarkable course of prices in the petroleum industry, which in part ran counter to price developments in general, may be shown effectively by index numbers with 1913 as a base. Table 5 shows the results of expressing the price changes in this manner.

TABLE 5.—THE COURSE OF PRICES IN THE PETROLEUM INDUSTRY
(Average prices for 1913 = 100)

	1913	1919	1920 1st Q.	1920 2nd Q.	1920 3rd Q.	1920 4th Q.

Lubs. Penn. Neutr. 200..	"	Cents p. gal.	27.0	35.0	22.5
Lubs. Okla. Neutr. 200..	"	" " "	17.6	27.3	21.8
Lubs. Penn. Cyl. Stk. 600.	"	" " "	33.5	48.5	26.0

The falling prices of fuel oil and lubricating oils during the latter portion of 1920, in the face of the maintenance of the price level for crude petroleum, seriously curtailed the margin of profit enjoyed by refineries in general and entirely wiped away this factor of safety in respect to many small refineries, especially the skimming plants in the south-central portion of the country. As a result of this circumstance and of complications growing out of the period of credit stringency through which the country has been passing, the mortality among refineries has been high in numbers. But, nevertheless, the refinery capacity of the United States is so over-expanded, and the country's petroleum products are so dominantly produced by refineries of 10,000 barrels daily capacity and above, that the rather wholesale closing of small refineries in certain sections of the country may not be expected to exert a far-reaching effect upon the productive capacity of the industry in the months ahead.

Summary

By way of summary, the outstanding features of the year were the following:

(1) The supply of crude petroleum, both from domestic and Mexican wells, increased surprisingly and led to conditions of moderate over-production toward the end of the year.

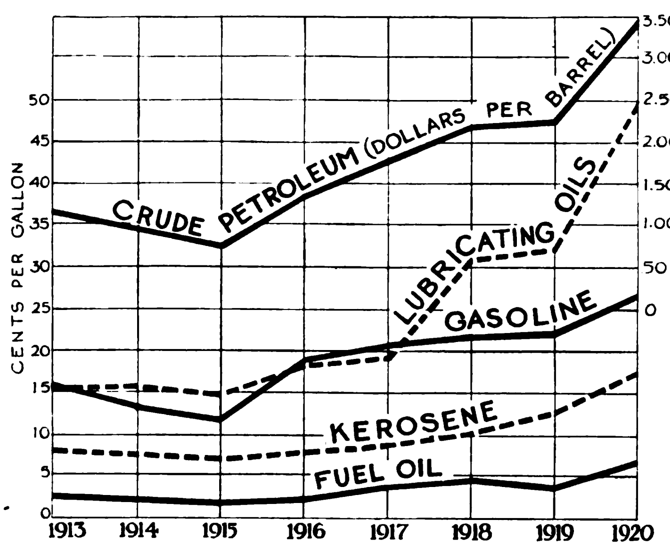

Fig. 7—Trend of the average price of crude petroleum and its principal products by years, 1913-1920

(2) The new production per well "brought in" in 1920 was less than in 1919, pointing to the necessity for intensive development if domestic production is to be maintained; toward the close of the year drilling operations were greatly curtailed.

(3) The supply of gasoline kept pace, but only with difficulty, with the greatly enlarged requirements of automotive transportation.

(4) The endpoint of gasoline notably increased during the year, this rise being accompanied by a lessened output of kerosene relative to the quantity of gasoline produced.

(5) A shortage of heavy-bodied lubricating oils developed during the early months of the year, which in turn led to greatly augmented production later on.

(6) Both crude petroleum and its principal products rose sharply in price to levels from which only fuel oil and lubricating oils partly receded.

(7) The oil industry was less affected by the period of industrial depression through which the country has been passing than most other activities, although a deferred effect has unmistakably been felt.

How the Automotive Industries Fared in 1920 Metal Market

Here you will find an explanation of the industrial statistics that have served only to confuse you during the last year. Also you will find statements of the use of metals in our industry and the prospects for 1921.

By William Crawford Hirsch*

A CURVE depicting the ups and downs of the iron, steel and non-ferrous metal markets in 1920 and one delineating the periods of prosperity and adversity in the automotive industries, would be as one egg is like another. The placing of this observation at the outset of this retrospect of metal market conditions in 1920, is prompted by the zeal with which statisticians, when the heyday of bloated values and fat premiums had vanished, sought to comfort the steel industry by stressing what they were pleased to call the minor importance of the automotive industries as a consuming outlet for iron and steel products. In the same breath in which they berated the automotive industries for having brought about the runaway steel market of the first half of 1920, they belittled the self same factor's importance as a buyer of steel by statistical legerdemain. The automotive industries consume only 2.6 per cent of the total steel ingot production. The automotive industries absorb only 3.5 per cent of the entire rolling mill output. These were some of the stones thrown into the steel industry's own garden. The deceptive character of these figures is all the more insidious because, standing by themselves, their inaccuracy is slight, while they are grossly misleading when employed to demonstrate the minor importance of the automotive industries in the steel market.

The measure of the automotive industries' support of the steel industry is **not one of tonnage but of dollars.** Conceding for the time being the correctness of the estimate that only 2.6 per cent of the steel ingot production went into automotive manufactures in 1920 (an estimate the shortcomings of which will become obvious later), the fact remains that the steel industry derived more gross and more net revenue in 1920 from the automotive industries than from any other source, not excluding the railroads. This is universally conceded by steel producers and very easily explained.

The automotive industries buy steel in highly finished form. The differential which automotive builders pay over ordinary black sheets for highly finished sheets, suitable for body, fender and radiator stock, is equivalent to the cost of two tons of rails for every three tons of such sheets. And this is only the differential over black sheets. When automobile sheets sold at record breaking prices last spring, a ton of this material represented a payment of approximately $350 to the rolling mill. At the same time railroads were paying $55 a ton for rails. Yet both rails and sheets are lumped as rolling mill products.

These preliminaries are merely intended to open the reader's eyes to the absurdity of a statement such as that the automotive industries consume only 3.5 per cent of the total rolling mill output. It would be just as logical to say that diamonds make up only a fraction of a per cent of the weight of the entire jewelry output.

Moreover, all these estimates are based on the weight of the steel in the finished automotive unit, multiplied by the number of such units reported to have been built in a given year. As a matter of fact, when the statement is made that the average passenger car contains 913 pounds of steel and 630 pounds of pig iron, the use of these figures as a basis to compute the amount of steel and iron purchased for the construction of this car is entirely unwarranted. The amount of scrap that results from cutting sheets to size and from machining cast or forged bars is so great that the tonnage purchased is far heavier than that represented in the finished product.

And what of the thousands of tons of steel that are absorbed by the machine tools and other equipment of automotive plants, to say nothing of tire, artificial leather and other accessory manufactories? To the steel statistician anything and everything that is tubular, is "oil country goods" wherefore he fails to credit automotive consumption with the thousands and thousands of tons of steel required to satisfy its needs in this direction. Because gasoline tanks and pumps are not part of the passenger car, truck or tractor, they have no place in his reckonings.

The course of events, however, has overtaken these statistical falsehoods and clearly established the undeniable fact that not only are the weal and woe of the iron, steel and non-ferrous metal markets indissolubly linked with the fortunes of the automotive industries but that, moreover, real, genuine prosperity in the former is predicated upon a like condition in the latter. Reviewing the trend of prices and conditions governing the markets for pig iron, steel products and non-ferrous metals in 1920, we find evidence after evidence of this. In fact, the year under review is divisible into two epochs, the first period coinciding with that of unalloyed prosperity in the automotive industries and the second marking a gradual transition from the prince to the pauper rôle. Tradition has it that the steel industry's repertory is made up of these two extreme parts and that it can play no other. If this is true, then it is condemned to play the part of the pauper until the automotive industries re-enter the stage as Lady Bountiful.

The year 1920 inherited from its predecessor a severe case of rich man's gout and this was aggravated by the utter disregard for price which those engaged in the automotive industries continued to display when it came to their quest for prompt deliveries of pig iron and steel products. It was nothing short of adding irony to insult

*Editor *Raw Materials*.

when those who were obtaining outrageously excessive prices for steel, pleaded that it was not their fault but must be charged to account of the automotive consumers, who were falling over one another in their mad scramble for supplies.

It was perfectly natural that automotive builders were anxious to maintain their production schedules and, when the railroad strikes began in April, they moved heaven and earth to obtain the necessary iron, steel, and non-ferrous metals for their operations. The transportation strikes furnished a blanket policy of insurance holding mills immune from liability for non-delivery of material contracted for. Much of this material, however, was turned out in spite of the scarcity of raw materials, and formed the sustenance of a premium market that soared and soared until its own top-heaviness caused its downfall.

The unnatural price levels established in this market together with the price schedule of the United States Steel Corporation, which remained unaltered throughout the year, and a somewhat higher range of values quoted by the representative "independents," constituted the tripartite price record that continued during the first half of the year. With the return of near-normal transportation conditions and a general awakening to the dangers of inflation, the premium market vanished and there remained the dual price condition of the Corporation and the representative "independents." This state of affairs persisted until October brought the first signs of a let-up in demand from the automotive industries and from then until the end of the year was consumed in a gradual wiping out of all differences in prices between the Corporation and "independents," with the result that the end of the year witnessed a virtually once more uniform price schedule, that of the Corporation.

A very modest estimate of the amount which the "independent" steel mills received in 1920 in excess of what they would have received, had they sold their output at the same price as the Corporation, is $250,000,000 to $350,000,000. When there is added to this the amount that was "cleaned up" by intermediaries in the form of premiums on top of premiums during the "famine" period, the amount paid by consumers for the output of the "independent" mills in excess of the Corporation's prices, may be put down as having been very close to $500,000,000. It is left to the reader's recollection of the days when it was nothing unusual to bring a "load" of steel in a Pullman compartment from Youngstown or Pittsburgh to Detroit, to estimate how much of this bill was defrayed by the automotive industries.

Course of the Pig Iron Market

With the exception of 1917, the present generation has not witnessed pig iron prices of the magnitude recorded last year. In a large measure blast furnace interests ascribe these phenomenal prices to the corresponding condition in the coke market in which July witnessed quotations of $18 for furnace coke, f. o. b. Connellsville ovens. This compares with an average price of approximately $1.75 in 1914. Aside from this influence and undoubtedly generally enhanced production costs resulting from increased freight rates, there was in evidence, however, a disposition on the part of some of the pig iron interests to force the establishment of a $50 pig iron market and to "hold it there." Foundry iron which had started the year at $38.50, valley furnace, gradually went higher and higher until in September $50 became a nominal quotation for at least a brief spell. When pig iron sellers sought to make this an actual instead of merely nominal quotation, consumers, especially automotive foundries, balked and the first of the "consumers' strikes" which have since then become fashionable, ensued. Certain pig iron interests excoriated those who dared to question the justice of and the justification for a $50 market and predicted "much higher price levels." At the close of the year, however, after 215 out of a total of 416 furnaces had gone out of blast, the price for No. 2 foundry was down to $33 and sellers were hunting in vain for buyers.

The year 1920 marked the entry into the ranks of pig iron producers of one of the large automotive interests. Reports that this factor was offering iron of his own manufacture, at prices below the general market, served to hasten the return to saner values. When the market approached the $50 level, quite a number of automotive foundries that were holding contracts for the delivery of pig iron at below $40, turned resellers.

The two grades which are chiefly used in automotive foundries established the following price record, which is compared with that of 1913, the last normal pre-war year.

Pig Iron Prices in 1913 and 1920

	Foundry No. 2 (Valley Furnace)		Malleable (Chicago)	
	1913	1920	1913	1920
January	$17.50	$38.50	$18.00	$40.50
February	17.00	41.00	17.25	42.75
March	16.50	42.00	17.25	43.50
April	15.50	42.50	17.00	43.50
May	14.75	44.00	16.00	43.50
June	14.25	45.00	15.75	43.50
July	14.00	45.00	14.75	45.25
August	14.00	47.75	15.00	46.50
September	14.00	50.00	15.00	46.50
October	14.00	46.75	15.25	46.00
November	13.50	40.75	14.75	42.00
December	13.50	33.50	14.50	33.00

History of Semi-finished Steel

From the point of view of the automotive industry, sheet bars in 1920 were more than ever the key commodity of the semi-finished steel market. This product represents the intermediate stage between the raw steel and the finished sheet and for this reason is always of greatest importance as a market criterion. But in 1920 the sheet bar assumed double importance to the large automotive interests for the simple reason that they not merely had to keep their eyes on the sheet bar market but actually were compelled to go on periodical sheet bar hunts. In the first half of the year it became almost a custom for passenger car builders to buy sheet bars from the bar rolling mills and furnish them for conversion to the sheet mills. Under normal conditions even the smallest of the sheet rolling mills were accustomed to buying their own sheet bars and selling the finished automobile sheets, making a legitimate profit not only on their conversion but also on the raw material. When the location of sheet bar tonnages obtainable at anywhere near reasonable prices became, however, a task that tried the most resourceful, these sheet manufacturers threw up the sponge and told the automotive purchasing agents that, if they wanted sheets, it was up to them to provide the bars. The latter, urged on by their production managers, lost sight completely of the United States Steel Corporation's sheet bar price of $42 and went out to get the material at any figure, with the result that many a sale of sizable tonnage was reported in June at $90 and, in a few isolated instances, sales at higher than $100 were reported to have been made. The following table of prices in 1920, compared with those in 1913, does not record these absurdly high levels which were paid in the form of a premium over the quoted market price; yet comparison with the levels that pre-

vailed in the last pre-war year, tells the story of the price orgy eloquently:

Prices of Open-Hearth Sheet Bars, Pittsburgh

	1913	1920
January	$29.25	$50.00
February	30.00	67.00
March	30.00	75.00
April	28.25	72.50
May	27.50	72.50
June	27.00	75.00
July	27.50	72.50
August	26.25	70.00
September	25.00	66.00
October	23.00	65.00
November	21.50	50.00
December	21.00	47.00

The story of sheet bars was typical of all forms of semi-finished steel, so that we may proceed to a consideration of the movement in the finished steel market.

Finished Steel Products

If automotive consumers paid swollen prices for sheet bars in 1920, they paid nothing short of a king's ransom for such automobile sheets as were obtainable in the finished state either from rolling mills or resellers. Reference has previously been made to the startling levels that were obtained for highly finished sheets but there was a brief period in mid-summer, when even ordinary No. 28 black sheets for early delivery were sought at as high as 15 cents.

According to *The Iron Age*, the total sheet production in 1920, exclusive of tin and terne plate, amounted to 2,600,000 gross tons. Of this tonnage, 85 per cent, or 2,200,000 tons, were sheets of 13 gage and thinner. Any one who followed the character of the buying last spring and summer, will concede that virtually all of the latter sheet went into passenger cars and of the 400,000 tons of sheets, 12 gage and thicker, the bulk undoubtedly was used for frames.

That the automotive industries consumed last year 2,000,000 tons of sheets, is a very conservative estimate. This is the equivalent of 4,480,000,000 pounds. At an assumed average price of 6½c. (which, in view of the price record, is very modest), this tonnage would represent an approximate outlay of close to $300,000,000, which, in itself, disposes of the absurd misstatements that the automotive industries constitute a small factor in the steel market.

The following table, contrasting 1913 with 1920 prices for No. 28 black sheets, does not record the startling premiums that obtained in the late spring and mid-summer:

No. 28 Black Sheets, Pittsburgh

	1913	1920
January	2.30	5.00
February	2.35	6.00
March	2.35	6.00
April	2.35	6.00
May	2.35	7.00
June	2.30	7.00
July	2.25	7.00
August	2.20	7.00
September	2.10	7.00
October	2.05	7.00
November	2.00	6.00
December	1.85	4.45

To cite the price records of other finished steel bought by the automotive industries, such as cold-rolled strip steel or of bolts and nuts, would be merely duplicating the performance of sheets. Up to the latter part of July, when the first indication of a slowing up in automotive cast its shadows before, any price was fair from the sellers' point of view. This was followed by a period of grim determination on the part of the independent producers to maintain the differentials which they had established over the Corporation's levels, but, in October, it became discernible to all that it was no longer possible to maintain these quotations even as purely nominal and, amid utter idleness, prices gradually shed their obesity.

Alloy Steels

The alloy steel industry, as constituted to-day, is really a creation of the automotive industries and utterly dependent upon the latter not merely for its partial support but for its very continuance. As the result of their serviceability in the making of axles, connecting rods, crankshafts, gears, steering knuckles, high tensile bolts and a variety of smaller parts, either forged or machined from hot- or cold-rolled or drawn bars, nickel-chromium steels came to the front in 1920. On the other hand, there appears to have been some diminishment in the use of vanadium in automobile steels. Metallurgical progress centered around the electric furnace and heat treatment methods and, while a number of complex ferroalloys were put on the market, none of these found practical employment in the automotive industries.

Prices for special alloy steels are and will always remain a matter of individual arrangement between sellers and consumers. They are specialties of varying analyses and into their cost enters, to some extent at least, the steel maker's reputation for metallurgical skill and accuracy. What happened in the alloy steel market last year may, however, be fairly judged by the price movement of ferromanganese which still remains the key alloy.

Ferromanganese Prices

	1913	1920
January	$68	$146
February	65	172

October	50	170
November	50	170
December	47	135

Non-ferrous Metals

Viewed in the retrospect, the year 1920 was one of orderly deflation in the non-ferrous metal markets. The writer of this review considers himself fortunate that he was not called upon to prepare this article last December when, under the spell of the wave of pessimism that prevailed at that time, annual résumés of the non-ferrous metal markets took on a much darker hue than appears warranted. The non-ferrous metal business is, far more so than the steel business, one of short-time financing and, whenever money becomes as tight as it did in the closing months of the year, forced liquidation is bound to give the market a funereal appearance. Then follows a calm survey of the statistical position and the invariable result is that the old law of supply and demand has once more worked for the best. Before considering the record of the market's key metal, copper, the 1920 history of aluminum may be briefly summarized because of the commanding position of the latter from the point of view of the automotive industries.

Aluminum's History in 1920

The year opened with the sun shining brightly in the automotive field and for several months the sole domestic producer could not satisfy the demand, although

working at full capacity. Here and there, odd lots of imported metal bobbed up but, up to the middle of July, the 32.75 cents price for No. 1 virgin ingots, 98 to 99 per cent pure, of the Aluminum Company of America was to all intents and purposes the market, the importers refusing to shade this price level more than a fraction of a cent, so long as it was clearly evident that the demand exceeded the supply. Fastidious automotive consumers hesitated, when foreign metal was offered to them at concessions from the domestic level. Some of the importations consisted of mixed lots that might and might not come up to analysis. The American interest announced an advance to 33 cents at the very time when the first signs of a slackening in the demand made themselves felt and then a veritable avalanche of imported aluminum began to inundate our shores. Not only England and France shipped metal and sheets here but Norway, Germany and other countries figured as sellers. Judging from some of the aluminum offers received from Germany, that country must have an even more plentiful supply of bauxite (the mineral from which aluminum is extracted) than of paper marks. Lower and lower went prices in the "outside" market until at the end of the year the metal was offered freely at 25 cents. Meanwhile, the American producer had instituted a spot price for immediate deliveries, several cents higher than the "outside" market but considerably below his contract price which was maintained intact for strategic reasons.

Imports of aluminum and aluminum manufactures in 1920 probably amounted to around $14,000,000, compared with about $9,000,000 in 1913 and $12,000,000 in 1919. The American producer is asking for the restoration of a duty of 7 cents a pound. In this, he is opposed by the consuming interests. Meanwhile, a new octopus has been born in the European aluminum industry, the Compagnie d'Alais which, after absorbing the Société Electrometallurgique Français, controls 90 per cent of the aluminum producing capacity of France, besides the works in Norway and a controlling interest in the Italian aluminum works.

The price record of aluminum, compared with that of 1913, is given here for the "outside" market:

Aluminum Prices for No. 1 Virgin Ingots, 98 to 99% Pure
(Outside Market)

October	20¼	29
November	19½	27¾
December	18¾	24

Copper's Eventful Course

The year 1920 inherited from its predecessor a surplus of refined and blister copper of 941,000,000 pounds and bequeathed to its successor a surplus of 874,000,000 pounds. These figures really tell the story of the movement in the red metal in a nutshell. The load inherited from 1919 was too heavy a burden and, as a result, the 19 cents price level at which electrolytic opened the year, sagged and sagged until at the close of December buyers at 13½ cents were as scarce as hens' teeth. Producers had recourse to every possible device to stem the downward course which did not become precipitate until October. They lowered refinery production from approximately 1,750,000,000 pounds in 1919 to 1,575,000,000 pounds in 1920. Ever so often the spokesmen of the copper industry would give out interviews that the demand from Europe for copper had at last set in and that it would not be long before England, France and Italy would literally eat up the surplus and, if they left any of the red metal over, Germany would lick the platter clean. But custom house returns failed to substantiate these predictions and exports showed only a slight improvement over 1919, much of the metal going abroad being strongly suspected of being shipped on consignment.

From the standpoint of the automotive consumer of copper, the most interesting development of the year was the activity of a research committee appointed by the copper producers to investigate the causes underlying the ailing copper market. This committee made the following report regarding copper consumption by the automotive industries:

> In no one industry has public ignorance of the merits of copper and brass been more costly than in automobiles. Since the first year of the war there has been a steady tendency toward iron products until the total amount of copper and brass now used in the average automobile is about 36 pounds. To this substitution in structural and working parts is attributed the tremendous increase in the automobile repair business in the last few years. The breaking down of cars turned out in the last five years is particularly noticeable in coast cities where salt air affects machinery not immune to rust. A notable exception to this war-time and post-war substitution is a certain large passenger car which the A. E. F. made famous in Europe. It contains 200 pounds of copper in striking contrast to another large and high-priced car that contains 30 pounds.

This is not the place to make suitable answer to these *ex-parte* statements which must be replied to in terms of tensile strength, elongation and specific gravity of the high grade alloy steels to which the copper committee refers as "iron products." Coming out of the mouths of the copper producers themselves, however, the fact may be put down that there has been a falling off in the consumption of copper in the unalloyed state in the automotive industries. That the tonnages of copper consumed in brass parts that enter into automobile manufacture is considerably greater than generally supposed, is certain. The statement recently made that the automotive industries consume approximately 75,000,000 pounds of brass a year or around 7 per cent of the total output, is based on altogether false premises. It takes no account, whatsoever, of the very large output of automotive castings, screw machine products, etc., that are made from secondary metal or so-called ingot metal which the foundries purchase from secondary refiners. A clear picture of the course of values in 1920 may be gained by means of the following table comparing 1920 prices with those of 1913.

Price for Electrolytic Copper, New York

	1913	1920
January	16¾	19
February	15¼	18⅝
March	15	18⅜
April	15½	18½
May	15⅝	18¼
June	14⅞	18
July	14½	18⅝
August	15⅝	18½
September	16½	18
October	16½	16¼
November	15½	14⅜
December	14½	13½

Highlights in the Tin Market

Tin is of chief interest to the automotive industries because it enters into solder and babbitt, although it is also used for the plating of radiator parts and, with copper and zinc, forms an essential constituent of bronze. The outstanding feature of the market was the tremendous accumulation of white metal alloys, such as babbitt and solder, which, when the slump came in October, were a drug on the market. The chief influences in the tin market were the kaleidoscopic changes in the value of the pound sterling, speculation both in London as well as here, and a paternal interest on the part of the Federated Malay States Government in the welfare of the Straits Settlement tin producers which led to the adoption of a quasi-valorization scheme that sooner or later must lead to disaster. Compared with 1913, the course of values was as follows:

Straits Tin, New York

	1913	1920
January	50	63
February	49	60
March	47	62
April	49	62
May	49	55
June	44	49
July	40	49
August	42	48
September	42	45
October	40	41
November	40	37
December	38	34

Ups and Downs in Lead Market

Because of the predominant use of lead in storage batteries and other automotive parts, the market for this metal was a true replica of the tide and ebb in the automotive industry. As a lead consumer, the latter is exceeded only by the paint industry. At one time there were heavy importations of foreign metal, the differential between the relatively high New York and the relatively low London market making such operations profitable for a brief spell. The entire domestic output was 525,000 short tons compared with 517,000 tons in the preceding year. Compared with 1913, the price movement was as follows:

Monthly Average Lead Prices, New York
(Am. Smelting & Refining Co.)

	1913	1920
January	4.35	8.32
February	4.35	8.75
March	4.35	9.21
April	4.40	9.25
May	4.36	8.65
June	4.35	8.24
July	4.37	8.20
August	4.63	8.83
September	4.75	8.52
October	4.45	7.47
November	4.34	6.61
December	4.06	4.94

Zinc Prices in Slow Descent

Zinc did not fare very much different from lead in 1920. The market's undertone, however, was always decidedly weak because of a considerable surplus which is an old sore in the zinc industry and which is no nearer to elimination now than it was two years ago. In spite of this millstone around the producer's neck, there were large importations during the year as the result of cheap offerings from Belgium and Germany in London. As will be seen from the following table, the market at the end of the year was very close to the levels of the pre-war period:

Prime Western Zinc, East St. Louis

	1913	1920
January	7	9¼
February	6¼	8¾
March	6	8⅝
April	5½	8¼
May	5¼	7¾
June	5	7½
July	5¼	7⅞
August	5⅝	8
September	5⅝	7¾
October	5¼	7¼
November	5⅛	6⅝
December	5	5⅞

Sundries of Metal Market

Nickel, which is used by one of the large battery producers, and also enters heavily into the manufacture of automotive steels as well as into plating of certain parts, remained virtually unchanged in price. Production has been lowered sharply so as to correspond with the diminished demand. Deputy Minister Thomas W. Gibson of the Ontario Department of Mines, referring to the expanded capacity of the nickel producing companies as one of the war's results, says that now "they feel all dressed up, but nowhere to go."

The antimony market moved from 10½ cents at the opening of the year to 5½ cents at the end, with the high at 11½ cents in February. The untoward exchange situation injured the Chinese producers more than the gradual deflation of values of which they had their first taste early in the year, when the business collapse in Japan put commercial and industrial affairs in the Orient at sixes and sevens.

The Outlook for 1921

The foregoing record of 1920 in the iron, steel and non-ferrous metal markets, together with such observations of the course of values which the interval since the beginning of the new year has permitted, afford a fairly definite basis on which to rear a sound purchasing program for 1921. While detached consideration of the price tables comparing 1913 prices with those of 1920, may in the case of pig iron and steel products lead to the conclusion that the spread between the levels which prevailed before the cataclysm of the world war, and those which marked the close of last year, is still too great, it will be well to remember that virtually all economists are agreed that there will be no complete return to pre-war commodity prices in our generation.

Further price adjustment is likely to be devoid of the spectacular and relatively slow. In many of the non-ferrous metals, values have declined to levels out of gear with the general run of basic commodities. Anticipation of reasonable wants appears to be justified, if for no other reason than that further postponement of buying is certain to lead to the accumulation of a large suppressed demand which, when it does make itself felt, can have but one result, i.e., to bring about an upward reaction in prices which would still longer delay the orderly process of a return to normal. Nothing is to be gained by a further drying up of the sources of supply. In spite of the ill-thought vaporings of this or that figure-juggling detractor of the importance of the automotive industries as a consumer of iron, steel and non-ferrous metals, the fact remains that to no other factor do the producers of these commodities look so much to make the smoke belch forth from their blast furnaces, smelteries, refineries, foundries and rolling mills than to full revival of automotive production and activity.

Present Status of German Automobile Industry

This article describes the engineering, social, and economic aspects of the German automobile industry at the present time. It points out the general tendencies in design and production and indicates the handicaps which are being encountered. 43 factories producing cars or trucks.

By Benno R. Dierfeld

THERE are at present 43 automobile factories in Germany, 14 of them building passenger cars and trucks, 20 of them producing only passenger cars and 9 factories building only motor trucks. The 34 works building passenger cars produce about 90 different models as listed in the following table:

10	car	types	below	16	brake	hp.
10	"	"	of	16	"	"
13	"	"	up to	22	"	"
15	"	"	" "	30	"	"
5	"	"	" "	35	"	"
7	"	"	" "	40	"	"
11	"	"	" "	45	"	"
16	"	"	" "	55-80	"	"

The table shows that cars of 22 to 30 brake hp. are very frequently built and that a large part of the German manufacturers obviously believe these car sizes to be most suitable for the German customers. On the other hand almost as many cars have engines of 45 brake hp. or larger, representing an opposite opinion of some of the larger factories. Thirteen works build a single model, 8 firms build 2 models, 6 firms 3 models each, and only 7 factories build more than 3 models. The stroke to bore ratio is very different and varies between 1.3 and 1.6; a united opinion about the most favorable ratio still does not seem to be existing at present, for different car types, built by one firm, show different stroke to bore ratio. The design of the German passenger cars does not differ materially from the outlines given in my article, "The German Passenger Car Industry After the War" (AUTOMOTIVE INDUSTRIES, May 27, 1920). The disk clutch is only used by five works and only one car has left-hand drive. Of course electric starting and lighting systems are applied to many cars, but the car prices then are very high. No important change can be found in the German passenger car market up to the present moment, but a car of revolutionary design now is completing its test runs and surely will cause a sensation when the first details are published; cycle cars, of course, show many innovations. The selling prices of passenger cars are not materially lower.

The 23 factories producing motor trucks build 51 truck types with the following engine powers:

4	truck	types	of	25	brake	hp.
2	"	"	"	28	"	"
5	"	"	"	30	"	"
7	"	"	"	35	"	"
2	"	"	"	38	"	"
4	"	"	"	40	"	"
5	"	"	"	42	"	"
9	"	"	"	45	"	"
8	truck	types	of	50	brake	hp.
2	"	"	"	55	"	"
2	"	"	"	60	"	"
1	"	"	"	86	"	"

An engine power of 30 to 50 hp. seems to be most suitable for the use of German customers. Eight firms only build 1 truck type, 5 firms 2 types, 4 firms 3 types, 4 firms 4 types and 1 firm 5 types. The stroke to bore ratio varies from 1.3 to 1.6, the number of revolutions from 800 to 1500 per min. Almost all cylinders have non-detachable L or T-head and the cooling is effected by pumps. Only 4 types have thermo-siphon cooling and 1 type air cooling. Pump lubrication and magneto ignition are always used. Clutches are in most cases of the simple cone design, only 1 type using double cone clutches and 7 types disk clutches running in oil. Almost all transmissions are of usual design and have four speeds and reverse, only 3 types having a 3-speed transmission; the rear axle drive is effected on 30 types by cardan shaft and bevel gears, on 20 types by two side chains, on 1 type by internal gear. One brake is arranged on the transmission and operated by pedal, the others are in the two rear wheels and operated by hand lever; the springs invariably are half elliptic and have in some cases small auxiliary springs. The steering post is located at the right side. The cast steel wheels have single plain rubber tires at the front and twin plain tires at the rear. Pneumatic tires for trucks are unknown in Germany. The loading capacity of the trucks varies from 1 to 5 tons and their speed from 15 to 60 kilometres (9.3 to 37 miles) per hour.

The economic or commercial situation of the German automobile industry is materially influenced by the exchange rate of the German mark; if the value of the mark advances the German works cannot export, for the German automobile prices are high on account of the high wages and the increasing costs of raw materials. Therefore, during the summer and autumn of 1920 a stoppage of the German automobile export occurred and the consequence was an increased supply for the home market. Dealers who formerly were very glad to receive any cars at all, were overwhelmed with car offers by the manufacturers. Sales on the home market were few. Not only has the customer's ability or inclination to buy gradually diminished, but also the customer calculated that automobile prices would drop as a result of overproduction. When old orders have been filled the only new market for trade will be the export to foreign countries. Therefore the German automobile industry wishes the annulment of the export duties, an

antiquated institution established at a time when the world market price was considerably higher than the home price, and with the purpose for preventing a clearance sale of German automobiles.

At present the value of the German mark has dropped home price, and with the purpose of preventing a clearance sale of German automobiles.

As it is impossible to import motor vehicles into Germany on account of the unfavorable exchange rate and other restrictions, some prominent American firms have successfully tried to gain a solid footing in Germany, not only on account of the German market, but also because Germany serves as a base to the large Russian market and to the other northern, eastern and southern countries. One year ago the International Harvester Co. founded at Bremen a branch and at Berlin another branch with workshops. Somewhat later the German automotive industry was alarmed by the announcement that almost 50 per cent of the shares of the preminent Caoutchouc and Guttapercha Co. at Hannover, producers of the famous Continental tires, had passed into the hands of the American Goodrich Rubber Co. Thus the American company takes advantage of the low wages in Germany (as compared with foreign wages and reference to the exchange rate of the mark), difficulties with importing the raw material are avoided and the customers buy really German built tires.

Ford Tractor to Be Produced in Germany

The American Ford Company has recently bought the Berlin factory of Ehrich and Graetz, which formerly produced lamps and during the war shell igniters, etc. At present this Berlin firm has sued for permission to import 2 trucks, 2 passenger cars and 8 sample Ford tractors, so that the German Government, farmers, etc., may be convinced of the suitability of these vehicles for German working conditions. The complete engines will be imported from America, while the other parts of the tractor will be manufactured in Germany by other German manufacturers according to the instructions of Ford.

The Ford tractor produced in Germany will be sold at 20,000 marks, if the production reaches 100 tractors a day. In the beginning, however, only 10 to 20 tractors per day will be produced and the selling price, of course, will be higher.

Later on the manufacturing of the Ford cars and trucks will be taken up; the German Ford works will provide with tractors and cars not only Germany but also the other European countries. All capital brought into Germany by the Ford company remains in the country, as does the profit arising from the enterprise. The Ford Co. also is liable to pay taxes to the German Government. Such enterprises only can be successful if the peculiar German conditions are carefully taken into account and if the factories selected for manufacturing really answer this purpose.

CAPITAL STOCK OF GERMAN MANUFACTURERS

Name of company	1914–15 marks	March, 1920 marks
Daimler Co. (Mercedes cars)	8,000,000	68,000,000
Adler Co.	13,000,000	36,000,000
Benz Co.	22,000,000	33,000,000
Hansa-Lloyd Co.	10,000,000	32,000,000
N. A. G. Co.	7,000,000	20,000,000
Wanderer Co.	3,500,000	10,500,000
Vomag Co.	5,250,000	10,000,000
Magirus Co.	2,000,000	9,000,000
Deutsche Lastautomobile Co.	1,000,000	8,000,000
Dux-Automobile Co.	1,500,000	7,000,000
Fahrzeugfabrik Eisenach (Dixi cars)	3,000,000	4,500,000
Duerkopp Co.	4,500,000	4,500,000
Presto Co.	1,500,000	4,000,000
Horch Co.	3,000,000	3,300,000
Mannesmann-Mulag Co.	2,000,000	3,000,000
Loeb Co.	2,000,000	2,500,000
Apollo Co.	1,000,000	2,300,000
Elite Co.	400,000	2,000,000

The gigantic growth of the American automobile industry raises the question as to whether the German automobile industry can remain capable of competition for the world's market, in the face of comparatively high German wages and the necessity to buy foreign raw materials at the low exchange rate of the mark.

The first and principal measure of the German industry in this respect is financial preparations for the future competition, i.e., the issue of new shares. The extent of this financial preparation may be seen from the accompanying table, representing a comparison between the share capitals of 1914-15 and the middle of March, 1920. This table is reprinted as a matter of reference.

Some of these figures have since been increased again and notice of new issues published, so that the real augmentation of the capital of the German automobile industry since 1915 may be estimated at about 215 million marks.

American Invasion Feared

The fear of the American invasion is indeed the chief reason for the financial preparation, mentioned above, and for the same reason three large German factories have formed a union with the name "Gemeinschaft Deutscher Automobilfabriken" abbreviated "G. D. A." and four smaller factories formed another union "Deutscher Automobil Konzern," abbreviated "D. A. K.," with the purpose of standardizing their designs and cheapening their production.

As the whole capital invested in the German automobile industry is not even as great as the capital of some few large American factories, it cannot hope to reach the giant American production figures and the cheap selling prices of some American cars. Therefore the only course for the larger part of the German automobile industry seems to be the production of "quality" automobiles that cannot be beaten on the world's market.

The social situation has produced very severe working conditions for the German automobile industry. Every factory must have a so-called "Betriebsrat" (factory-soviet), that is elected by the workmen representing employees and according to the law has the following duties:

The factory soviet is bound to assist the manager in his duties, to advance the performances of the workmen and the production of the factory, to further the agreement with the workmen and between workmen and manager. But in practice the factory soviets have frequently caused impossible situations from the manufacturing and financial viewpoints.

German Dealers Have Their Troubles

The situation of the German automobile dealer is rather difficult at present. While after the war the importance of the automobile increased owing to service difficulties of the railways, the automobile industry could not answer the heavy demands, because its capacity of production was decreased by very different factors: eight-hour working day, diminishing of working inclination and working intensity, numberless strikes, checking influence of the factory soviets and last but not least the coal scarcity. Therefore, the manufacturing costs were advanced to an unprecedented level, whereas the production dropped as to quantity and frequently also as to quality.

(*Continued on page 421*)

The Trend of Airplane Design

(*Continued from page* 364)

senger—that seems to have merit. This plane carries one person, handles exceptionally well and is economical. It is a biplane, powered with a three-cylinder Lawrence air-cooled engine of 60 horsepower.

Commercial Carriers.—There has been several interesting commercial land planes developed that give promise of more extensive utilization during the coming year. Among these are the Martin and the Lamson.

As predicted, however, seaplane commercial carrier development has been extensive. The Aeromarine Plane and Motor Co. are at present the prime movers in the field and have done meritorious pioneer work in converting Navy F59 and H52 L seaplanes into commercial ships. These planes are well adapted to commercial work, and will doubtless form the basis of redesigned carriers when the supply from the Navy is used up.

Miscellaneous Developments.—Considerable work has been done along the line of investigating possibilities of high speeds at high altitudes by means of engine superchargers. The present conclusion is that superchargers will be advantageous on fighting planes, where high altitudes and high speeds are a prime essential. For commercial carriers it is not believed that superchargers will come into any extensive use.

Few new engines have appeared, chiefly because there has been no great demand. Packard has developed several standard designs of merit, and the designers of the Lawrance 3-cylinder radial air-cooled engine are bringing out a 9-cylinder engine of similar construction and greater horsepower. This latter type possesses several points of great merit, and it is believed a very satisfactory plane will be produced around it.

The Army has been experimenting with variable pitch and reversible propellers. These are advantageous in securing maximum efficiency, and will decrease the landing run. These reversible and variable pitch propellors are an important development and if mechanical problems are solved will do much to advance aviation.

Many experiments are being conducted on parachutes; and out of them satisfactory and safe types are being produced. It is believed that airplanes will eventually be designed so that all occupants have parachutes; and a means of ready egress from the plane in case of necessity. Considerable educational and development work will be required, however, to bring this condition about.

Fireproofing.—Airplane fabrics previously were always inflammable. This was reduced somewhat by nitrate dopes. During the past year, however, methods of fireproofing airplane covering have been developed; and these have been shown by test to reduce the fire hazard. Gasoline, of course, is the greatest point of danger; and the hazard here can be reduced, and is being reduced by use of leak proof tanks. The future airplane will be nearly fireproof, and will carry its fuel supply either in leak proof tanks or in such a manner that it can be dropped from the ship in time of fire.

As will be noted from the preceding, airplane development is proceeding as well as can be expected under existing conditions. Government contracts are serving as the basis of the business, and manufacturers are alive to every business opportunity and carrying-on as well as circumstances merit. That the development is not up to the wild hopes of the armistice period is logical—that it will be, certain.

Specifications of American Aircraft Engines—1920-21

Labor Statistics Indicate Recent Industrial Trends

Strikes occurred with about the same degree of frequency during 1920 as in past years, but a larger percentage were fought over increased wages. A. F. of L. membership now 4,078,740. Number of members participating in strikes 213% greater than ever before. 3,473,466 men are out of work, and wage reductions are common. Interesting conclusions drawn.

By Norman G. Shidle

THE striking thing about any compilation of labor statistics is the absence of data concerning the really vital features of human relationships in industry. The figures available are of interest chiefly as an indication of some of the broader trends of the times and as a somewhat complete record of the activities of labor which is organized in some form.

Insofar as the activities of organized labor are similar to the thoughts and desires of all the men who work, the labor statistics available are valuable. Where these activities are merely the expression of the organized groups which conduct them, their importance is accordingly diminished. It is useless to approach any discussion of current labor statistics without a full realization of these limitations.

Certain very definite values, however, may be obtained from a survey of such statistics. It is with a view to gaining those values that the present data are presented in a form calculated to bring out the points most pertinent to the larger discussion of labor and industrial relations problems in general.

Labor unrest as manifested in its most virulent form, that of strikes, showed no signs of materially decreasing during 1920. The figures given here are complete for the first three-quarters of 1920, and were compiled by the Bureau of Labor Statistics of the Department of Labor. Following is the record of strikes and lockouts during the last five years.

	Strikes	Lockouts
1916	3,681	108
1917	4,324	126
1918	3,232	105
1919	3,253	121
1920 (¾ yr.)	2,724	67

While figures for the last quarter of 1920 are not yet available, it is probable that this quarter will show a relatively small number of strikes as compared with the corresponding period of the preceding year. The large amount of unemployment and the consequent decline in the fighting power of the unions doubtless has had an effect upon the number of strikes. Since this decrease in the number of strikes, however, is due to the change of economic conditions and not to any fundamental adjustment in the relations between capital and labor, it is fair to say that the strike records show industrial unrest to be about the same as in previous years.

PRINCIPAL CAUSES OF STRIKES AND LOCKOUTS 1916, 1917, 1918, 1919, AND FIRST THREE-QUARTERS OF 1920
(Approximate Percentages)

Fig. 1

Causes of Strikes

The causes of strikes as announced in the statistics constitute the points over which came the actual breaks between employer and employee. They do not constitute the fundamental reasons for industrial unrest.

A larger percentage of strikes was caused in 1920 by the single issue of wages than in any previous year. Forty-five and one-half per cent of all the strikes which occurred in 1920 hinged upon a demand for increased wages alone, while 59.47 per cent of the strikes involved the question of wages in one form or another.

The predominance of the wage question as the breaking point of strikes made other causes diminish proportionately. There is no other single cause which stood out prominently, the most important of the causes not involving wages in any form being the question of recognition of the union, only 6.52 per cent of

INDUSTRY GROUPS IN WHICH THE LARGEST NUMBER OF STRIKES AND LOCKOUTS OCCURRED IN 1916, 1917, 1918, 1919, AND FIRST THREE-QUARTERS OF 1920

Industry	STRIKES					LOCKOUTS					Grand Total
	1916	1917	1918	1919	1920	1916	1917	1918	1919	1920

Fig. 2

the conflicts being precipitated on this particular issue.

An examination of the other strike causes shows a similarity in proportion to those of other years both in numbers and percentages. The chief conclusion to be drawn from a study of this table is that the questions over which the actual break in relations usually come assume about the same relative importance each year. It would seem to indicate a rather discouraging tendency on the part of both organized labor and some employers to "fight it out along these lines if it takes . . . forever."

The record of lockouts shows nearly the same tendencies. During 1920 the percentage of lockouts occasioned by demands for increased wages increased 10 per cent, but this merely indicates that many of the miscellaneous troubles of past years have been concentrated into this one point by the labor unions. The percentage of lockouts because of demands on the part of the workmen for union recognition continue in practically the same proportion, last year being 25.39 per cent and the year before 25.69 per cent.

A larger percentage of lockouts involved working conditions in 1920, 4.47 per cent being attributed to this cause.

Building Trades Lead Striking Groups

The number of strikes occurring in some of the chief industrial groups is shown in Fig. 2. In 1920 the building trades conducted the largest number of strikes, while the clothing workers suffered the greatest number of lockouts. The leading industry groups as to number of strikes conducted during the first three-quarters of 1920 line up as follows:

Building trades	433
Metal trades	331
Transportation	238
Clothing industry	215
Textile industry	204

Comparing these figures with those of past years, it becomes evident that there has been a considerable decrease of trouble in the metal trades during 1920. In 1919 the metal workers struck 527 times, in 1920 only 331. The building trades, on the other hand, though leading the list in 1920, had about the same number of strikes as in past years.

Taking a period of five years, however, including 1920, the metal trades have caused the most troubles. The list for this longer period appears in this order, including both strikes and lockouts:

Metal trades	2463
Building trades	2177
Clothing	1689
Mining	1302
Transportation	1273

There has been a fall in the number of mining strikes during the last year, but the seriousness of the situation in this industry has probably increased materially, nevertheless.

Strikes of Less Duration

Fig. 3 shows the duration of strikes during the last five years. In 1919, 29.25 per cent of the strikes listed in this table lasted from one to three months, while in 1920 this percentage was reduced to 24.65 per cent. The percentage of those lasting from 1 to 2 weeks, however, increased during 1920 from 15.78 per cent to 18.70 per cent. These two periods represent the lengths of time during which the greatest number of strikes endured.

The figures for five years bear out this tendency, as 1305 strikes during that period lasted from 1 to 3 months and 1257 lasted from 1 to 2 weeks.

The figures on lockouts indicate that once a lockout starts it has an excellent chance of continuing for a considerable length of time; a better chance, in fact, than the strike. The reason for the new impetus given to strikes after the two-week period is that the payment of strike benefits by the union begins at that time.

The figures for lockouts, however, show that in 1919 52 per cent of the lockouts lasted from 1 to 3 months, while only 29 per cent of the strikes endured that long. Similarly in 1920, 31 per cent of the lockouts lasted as long as this and only 24 per cent of the strikes. Moreover, the total figures for five years show that nearly 19 per cent of the lockouts lasted more than three months, while only 5.7 per cent of the strikes were carried on through a period of equal length. This indicates that the economic power of the employer is usually in a better position to withstand a long industrial battle than is that of the labor union. It is obvious, however, that the ability to win a strike may not constitute the *summum bonum* of a successful labor policy.

New York Has Most Trouble

New York and Pennsylvania maintain their unenviable position as leaders in the number of industrial disputes

DURATION OF STRIKES AND LOCKOUTS ENDING IN 1916, 1917, 1918, 1919, AND FIRST THREE-QUARTERS OF 1920

Fig. 4

during the first three-quarters of 1920, as shown by Fig. 4. This is rather to be expected, however, since the number of strikes is always likely to vary with the degree of labor organization and both of these states are comparatively highly organized.

Michigan, an important industrial State also, is low in the list of industrial disputes resulting in strikes. This is probably due to the fact that organized labor has a comparatively small hold in that State as compared with Pennsylvania and New York. The actual number of strikes would naturally be lower in Michigan because of its smaller industrial population, but the proportionate number is also somewhat smaller.

Although fifth in the list of total strikes, Ohio has had more lockouts than any State except New York.

For five years the total number of strikes in the States that have been most troubled in this respect is as follows:

New York	2915
Pennsylvania	1818
Massachusetts	1799
Illinois	1116
Ohio	1113

Fig. 5

Most Strikes Begin in April

Fig. 5 shows the number of strikes beginning in each month. It will be noted that the largest number begin in the spring months in general and in April and May in particular. This fact can be attributed to two causes. First, that less physical hardship accrues to the workman when a strike is conducted in warm weather. Second, many union agreements terminate in the months of April and May and disputes frequently occur in the making of a new agreement.

Who Is Winning?

Figures for the half of 1920, shown in Fig. 6, indicate that the battle between employers and employees is still about a draw in so far as the winning of strikes is concerned. The figures at hand show that an exactly equal number was won by both sides during this period.

It should be noted, however, that every time a strike is compromised the employer has, in a sense, lost, since

RESULTS OF STRIKES AND LOCKOUTS ENDING IN 1916, 1917, 1918, 1919, AND FIRST OF 1920

RESULTS	STRIKES ENDING IN—					LOCKOUTS ENDING IN—				
	1916	1917	1918	1919	1920	1916	1917	1918	1919	1920
In favor of employers	727	382	450	624	136	21	13	6	18	8

Fig. 6

labor has gained something which it did not have under the previous *status quo*. And even when the employer wins a strike, he has lost in charges for overhead expense, lost production, etc. Thus it would seem to be apparent that the employer, at least, never has anything to gain from a strike, whether he is strong enough to "win" it technically or not.

For this reason, if not for many others, it is not likely to be advantageous to the employer to lay an excess of emphasis upon the "fighting" phases of his future labor policy. Every time there is a pitched battle, he loses. The very fact that he has capital invested in plant and equipment makes the cards stacked against him.

A. F. of L. Statistics

The statistics concerning the American Federation of Labor are compiled upon a fiscal year basis, the fiscal year of this organization being June 1 to June 1. Consequently the figures presented here for 1920 are really for 1919-1920. Fig. 7 shows the growth of the A. F. of L. as to charters and membership. A gain in membership of 818,740 is recorded during the last year, bringing the total membership up to 4,078,740.

The figures show a net gain of about 4000 charters for the year, approximately 37,000 local unions now being affiliated with the Federation. The chart shown in Fig. 8 depicts the growth of the A. F. of L. since its founding in 1881.

It is probable that some drop in membership will be noted when the figures for 1921 appear next June, since an industrial depression of the present kind always has a definite effect upon union membership. This is largely a matter of inability to pay dues and the necessity for getting work of some kind to tide over the bad times, whether it be in conformity with union regulations or not. While union officials will not officially admit that they expect a drop in membership, there is little doubt but that they realize the very strong possibility of such a change.

The strike statistics of the A. F. of L., covering a period of ten years, shown in Fig. 9, present some interesting facts. The number of strikes decreased during 1920, but the numbers involved increased 213 per cent, as compared with the number involved during the previous year. Nearly two million men were involved in the strikes conducted by the A. F. of L. during 1920, nearly two-thirds as many as comprised the entire citizen army raised by the United States to fight the war against Germany and her allies.

In other words, the A. F. of L. was able to muster 213 per cent more striking power in 1920 than ever before. And as a result of this increased striking power, it benefited 188 per cent more men than before.

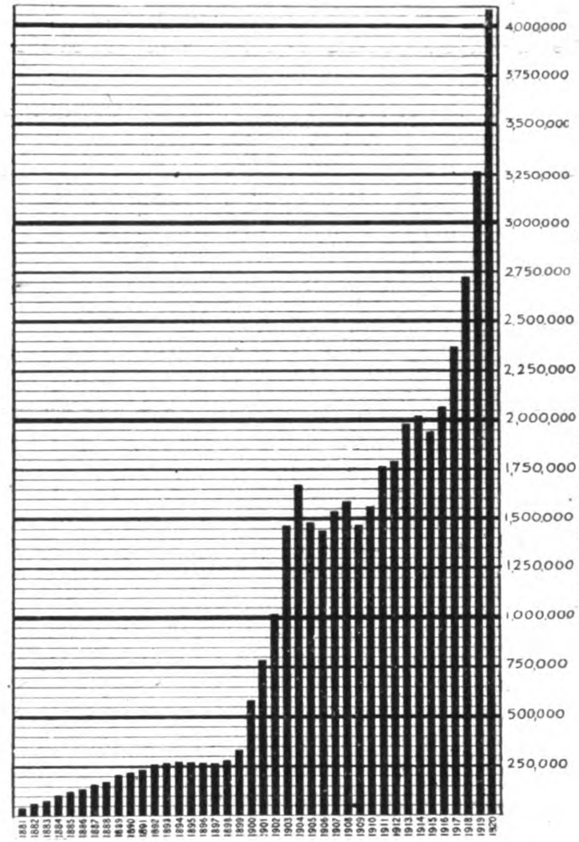

Fig. 8—Membership of American Federation of Labor 1881 *to* 1920

Cost of Strikes

The cost of conducting these strikes during 1920, although larger in the aggregate than during 1919 and 1918, was not as large as the aggregate for 1911, 1913 and 1915 when far less men were involved and benefited.

STATISTICS CONCERNING AMERICAN FEDERATION OF LABOR

	National and International Unions	Local Unions	Charters Issued	Charters Surrendered	Gain in Membership
1911	...	......	2,345	1,358	117,568
1912	112	20,964	2,388	1,422	216,012
1913	111	20,046	2,682	1,348	295,695
1914	110	21,460	2,578	1,351	62,822

1919	111	33,852	6,743	1,719	825,449
1920	110	37,000	5,449	1,639	818,740

Fig. 7

The total cost of strikes to the A. F. of L. during the last ten years has been $28,581,587. This is a staggering total when interpreted in terms of economic loss. When it is remembered that as much has probably been expended by employers, either directly or indirectly, in combating the activities of this organization the figures present a startling total, and a rather practical indictment of the present methods of conducting industrial relationships.

There is no ready made plan that can be adopted to eliminate this prodigious waste, but a constant and conscientious study of all the factors involved in human relationships in industry will gradually reduce the sums expended to organize and equip industrial fighting machines. Merely fighting the unions, without building very definitely in a constructive way, offers no solution to the labor problem; the problem which involves this enormous economic waste.

There are two ways of combating the problem. The one, to organize funds and forces with which to do battle with labor and its organizations which make certain demands inconsistent with efficient production and true economic service. The other, to study the fundamental causes which underlie industrial unrest, investigate and experiment in methods of eliminating those causes, and seek through hard work and thoughtfulness to bring human relationships in industry to a sane and normal condition mutually satisfactory to employer and employee.

Certainly the sum of about $60,000,000 expended in industrial warfare during the last ten years could have been more effectively and beneficially used if employers had been able to work out in a practical way some

AMERICAN FEDERATION OF LABOR STRIKE STATISTICS

	Number of Strikes	Strikes Won	Strikes Lost	Strikes Compromised	Strikes Pending	Number Involved	Number Benefitted	Cost of Strikes

Fig. 9

method of handling human relationships which would give every man a real opportunity for individual development and a square deal in every phase of his contact with the factory and the industry.

A Comparison

While all of the strikes listed by the Department of Labor are not, of course, A. F. of L. strikes, it is likely that a good proportion of them are, since the A. F. of L. is by far the largest labor organization in this country. And the vast majority of strikes are conducted by organized labor. The graphic chart shown in Fig. 10 presents the results of strikes during the years of 1916, 1917, 1918 and 1919 as shown by the figures of the Bureau of Labor Statistics and by the A. F. of L. While it is not to be expected that these curves would coincide, it would be reasonable to expect that some similarity of proportion would exist between the two.

The relative position of the lines is of interest in connection with this chart—not the actual figures. For example, granting that strikes seldom occur except when employees are organized and that the A. F. of L. includes the vast majority of organized employees in this country, it would follow that the proportion of strikes won by employers in A. F. of L. strikes would be relatively the same as the percentage of strikes won by employers in all the strikes recorded, and similarly, in regard to the strikes won by employees and strikes compromised.

The chart shows, however, that in the case of the Bureau of Labor statistics figures the number of strikes won by employers and employees, for instance, was almost the same in 1916, while the A. F. of L. figures show the number won by employees to be about nineteen times as great as the number won by employers. The relation may be expressed in a proportion which brings out clearly the divergence:

Employers won: employees won: compromised:
1:20:3 (A. F. of L. figures)
1:1 1/58:1 5/58 (Labor Dept. figures)

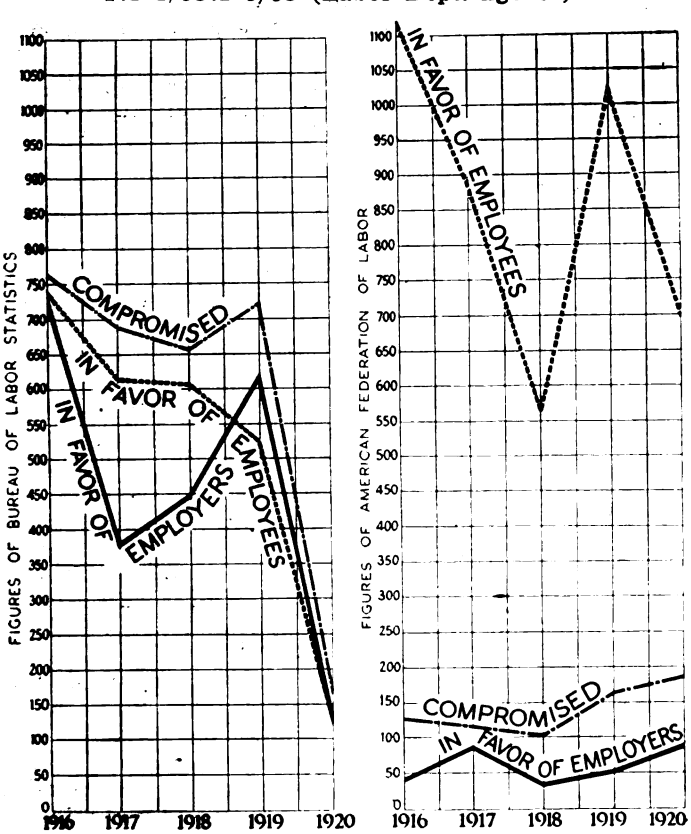

Fig. 10

A similar divergence is noted in the examination of figures for other years. The number of strikes won by employees in the A. F. of L. curve never approaches even closely the curve of strikes won by employers, while on the other chart this first line crosses the latter at one point and practically meets it at two others.

This case is cited chiefly as an example of the difficulties which are encountered in attempting to reach any definite conclusions in regard to labor problems on the basis of published statistics. The absence of standards of compilation and definition of terms renders it almost impossible to obtain anything like accurate figures in a great many cases.

Unemployment

The recent survey of unemployment made by the U. S. Employment Service presents the best figures available. This was, in fact, a survey of employment rather than of unemployment. The number of employees at work in the various plants throughout the country was determined and the total subtracted from a similar total of a year before.

It was found that 3,473,466 less persons were employed than a year ago. It is reasonable to take this figure as a close estimate of the number of unemployed in the United States at the time of the survey, which ended about Jan. 25.

This is true because all the industries and all the States throughout the country were covered by the survey. The only place men could have gone without being unemployed now is back to the farms. Since most of the extra farm work was over before the survey started, and since the survey covered the entire country, nearly this number of men must be regarded as unemployed at present.

The automobile trade showed the biggest reduction with a loss of 69 per cent, while the building trades were second with 52 per cent. Following is a list of reductions in some of the chief industries:

	Per cent
Automobile and accessory	69
Building trades	52
Textile	35.5
Leather	35
Lumber and house furniture	32
Metal trades, foundries, etc.	30.5
Packing	19
Clay, glass, cement, etc.	19

Michigan showed a greater proportion of reduction than any other State, with 82 per cent less employees than a year ago. This does not necessarily mean that all these idle men are still in the State of Michigan, but it does mean that they are probably idle somewhere. Following is the percentage of reduction in some of the chief industrial States:

	Per cent
Michigan	82
Ohio	50
Indiana	50
Illinois	44
Connecticut	43
Massachusetts	38
Wisconsin	32
New York	28
New Jersey	22

It is worth while to consider these figures concerning unemployment in connection with those concerning strikes and industrial unrest. An industrial condition such as prevails at the present time makes less blatant the voice of organized labor and in that sense promises for the time being less virulent labor trouble. It may be said that industrial depression reduces unrest so far as organized labor is concerned.

At the same time, a knowledge of human nature leads to the belief that industrial depression tends to increase unrest so far as the individual is concerned. Henry L. Doherty, president of the Cities Service Co. of New York, recently voiced this idea when he said in effect that he believed hunger to be more provocative of radicalism than high wages and plenty of work. It is natural for the man who is out of work and in trouble to come rapidly to the conclusion that something is wrong with the world. He will probably come to this conclusion through a successive series of psychological reactions than through any ordered method of reasoning, but if he is "out of luck" long enough he is almost certain to arrive there.

And just as it is necessary to work from the individual to the group in seeking to make permanent adjustment of human relationships in industry, so is the unrest which germinates and grows in a number of individuals likely in the long run to be more troublesome and potent than even the organized labor movement which begins with the group and works down to the individual.

The figures on strikes are printed in this article. The figures on industrial unrest as comprised in the more important factors of individual convictions and reactions can never be gathered. But they are none the less important and must be recognized and seriously considered, even though immediate circumstances show on the surface a cessation of active industrial unrest. It is for this reason that attention is called to them in this article, even though statistics cannot be compiled to accompany the discussion. It brings again to light the idea that a study of the individual and the proper attention to his development and desires is the first requisite in attempting to find a permanent solution to labor difficulties.

Wages and Cost of Living

Wages are now generally in a state of flux, so that wage statistics which might have been compiled yesterday would not be a true picture of the condition to-day. Moreover, general wage surveys, by whomever made, are usually open to so many criticisms and objections as to render them of comparatively minor value.

Cost of living surveys are open to the same criticism. Yet there is a certain value in surveys made at stated periods on the same basis by a single competent agency. It is almost impossible, however, to get satisfactory statistics upon which to compare in a general way cost of living and wages. It may be very possible and valuable, however, to make such comparison in a specific case or for a small unit.

With this thought in mind, the chart shown in Fig. 11 is presented. It shows the average rise and fall of the cost of living in 19 cities, all important in the automotive industry, from 1914 to 1920 inclusive. The chart has been prepared on the basis of figures compiled according to stable standards each year by the Bureau of Labor Statistics.

Similar wage scales, prepared by various other agencies, vary so materially that it has not been advisable to attempt the charting of a wage curve. It is possible, however, for any particular plant to plot its own wage curve along with the cost of living curve.

Wage Reductions

No complete data are available on wage reductions, but a survey of a large number of automotive plants reveals some general tendencies. The chief question concerns the time at which wages should be reduced and still give both employer and employee a square deal in the matter.

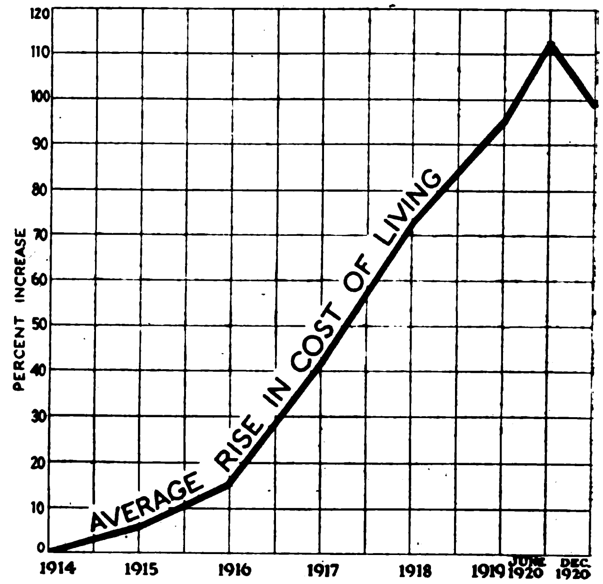

Fig. 11

Most factories have already reduced wages in one way or another. Even aside from reductions in working time, which temporarily reduce wages, a majority of firms have already made an actual cut in wages. There are still a number of firms, however, which have maintained wage scales up to the present time and which do not contemplate reductions in the immediate future unless there is a distinct drop in cost of living prices.

There has been great variation, however, both in the size of reductions made and in the method of making them. Some manufacturers have put the facts of the situation squarely before their employees and have taken considerable pains to sell them on the idea that reductions are necessary.

Others have simply posted a notice that reductions were to go into effect and stated how great the reduction would be.

Still others have discharged the men and superficially shut down their plant, to re-open it the next day and hire men back at lower rates.

Hours of Work

The question of hours has rather been reversed within recent months. Workmen have been desiring to work more hours than manufacturers have been able to allow them. This is the general condition at the present time.

In some cases, however, manufacturers have been coupling demands for increased working hours with demands for decreased wages. In other words, they indicate that the real reason for shutting down the plant is not lack of orders, but a desire to take advantage of the present situation to "put labor in its place."

This latter situation, however, does not apply to the automotive industry, so far as can be learned, and is merely mentioned as an indication of what is being done by some manufacturers in other lines of work.

Personnel Work and Shop Committees

There has been a falling off in the amount of "welfare" and personnel work being done in many plants since the beginning of the business depression. It is natural that this work should be contracted to a certain extent along with the other activities of the manufacturing plant, but in some places the curtailment in this department has been in much larger proportion than in any other department.

It will undoubtedly mean a great saving of wasted money in some plants to dispense with ill-conceived and not very effective "welfare" work. But even a superficial study of the situation shows that the over-curtailment of intelligent employment and personnel work will work great harm in the long run. As pointed out previously in AUTOMOTIVE INDUSTRIES, the present time offers an unusual opportunity for the manufacturer to put his house in order as regards industrial relations. By effective and intelligent personnel work in building his force back to normal, he can get together an organization of efficient, enthusiastic workers such as he has long been unable to obtain.

And for the very reason that many manufacturers will take advantage of the present situation to "get back at labor," the manufacturer who operates now on a real "square deal" basis will find himself in a very strong position when normal production is again resumed.

Shop committees have been abandoned in a few cases, but most plants which have had in operation an employees' representation plan for a considerable length of time are still operating on that basis. The present time will be one of real test for many of these plans, and some of those which have been operated most effectively and which were installed because the management honestly desired to consult with its employees and to give them a normal channel through which to obtain a practical working out of the "square deal" idea give every indication of weathering the present storm.

As stated at the beginning of this article, the unfortunate part about labor statistics is the utter absence of vital ones and the rather confused condition of many of those which are compiled. This is, of course, to be expected when dealing with anything so complex as the human element, but it is possible, nevertheless, for better and more valuable records to be developed in the future.

An Analysis of the Farm Lighting Plant Industry

(*Continued from page* 395)

leaving only an overcharging switch and sometimes a "restart" button exposed, the latter being used after a trouble stop has been made and the difficulty remedied. A noteworthy feature in connection with full automatic systems has been recently introduced by one manufacturer whereby the automatic control is instantly removable and may thus be sent to a service depot for repairs.

Engine Types.—Over 90 per cent of the engines used have one cylinder, 3 h.p. being the average maximum power for this class. Two cylinder engines are used with powers ranging between 3 and 8 h.p., fours between 8 and 20 h.p. and sixes for sizes larger. Only 4 per cent have two-stroke cycle engines, one is a semi-Diesel and the remainder are conventional four-stroke cycle engines, having low compression ratios to make them suitable for kerosene operation.

Air cooling is used on only 11 per cent of the models. Four are cooled by combination air and water, one uses oil for a cooling medium and the remainder are cooled by water circulating through an automobile type radiator or simple cooling tank.

The majority of four-stroke cycle engines use the poppet valve. Several use a rotating sleeve valve, one a Knight reciprocating sleeve, one a rotating disk valve.

Lubrication is most frequently by the conventional splash system. Ten per cent have pressure feed, especially the sleeve valve engines. Others use sight feeds, oil rings or oil cups. Babbitted bearings, frequently die-cast, are used most extensively although anti-friction bearings are becoming more general, being used for crank-pin bearings in some cases.

Over 25 per cent of the units are equipped with high-tension magnetos. Some of these are of the oscillating type. The remaining ignition systems consist of the plain battery-coil type.

The quality of engineering reflected by some of the engine designs compares quite favorably with the most advanced automobile practice. This is especially true of air cooling, aluminum pistons, reduction in inertia forces and the silencing of overhead valve engines.

Originally all plants were hand cranked. Now less than 10 per cent are so cranked. The progress of the present points to the development of full automatic systems. There are but 10 per cent of these now. As soon as electric plants are regarded as an electric service rather than a machine, more and more of our models will become automatic.

Present Status of German Automobile Industry

(*Continued from page* 413)

The enormous advancing of car prices, resulted in an annulment of signed delivery contracts by the factories described by me in my article of May 27, and the dealers came into a very difficult situation, because they had to arrange matters on the one hand with the customers, to whom only the dealer is responsible, on the other hand with the manufacturers. The result was many law suits and heavy expense. Consequently the German Automobile Dealers' Association was called upon to conciliate the strongly conflicting interests. The good results of the sales work done by the dealers were lost in large part. Their earnings furthermore were injured by the fact that the manufacturers endeavored to decrease the discount, in proportion to the advanced prices, in spite of the fact that the dealer had correspondingly advanced expenses.

The direct sale of army trucks and cars to the customers and to the motor traffic companies in a certain degree led to a disconnection of the automobile dealers and to a diminishing of their income. It also had the result, that casual dealers came in devoting only part of their time to the automobile trade. These men were interested only in making high profits immediately and thus lessened the earnings of the legitimate trade. In addition to this, the dealer did not receive any fuel from the government and was compelled to buy fuel in illicit trading at very expensive prices if he wanted to make a demonstration run for a customer. Consequently the German dealer has had a very hard task during recent months.

The repair shops essentially were subject to the same inconveniences as the factories, with the result that the working forces were systematically diminished or the shops shut completely.

The garage business, however, was very satisfactory on account of the large number of cars returning from the war and passing to the automobile trade.

The 1921 Statistical Number

IN placing before you our 1921 edition of AUTOMOTIVE INDUSTRIES STATISTICAL NUMBER we have some misgivings. It is not that we have spared expense and effort to make our work all that it should be, but rather that in this fast growing industry we sometimes find ourselves in doubt as to what we can do that will be of most benefit to the industry.

Each year brings forth new phases of our industry—new industries within our own. There is still rapid development in what might be called the fundamentals of the great industry. The practice and trade lines have not as yet been stabilized to the extent of older industries. On all sides there are problems.

It has been necessary to make choice as to subjects to be developed. After making the selection every endeavor has been made to present the best information available. Care has been exercised in making this information accurate, even to the extent of excluding some last minute data which could not be checked. There may be some errors. We hope not.

We will welcome from any user of the STATISTICAL NUMBER suggestions for future editions.

The Engineering Value of Statistics

THE value of statistics to the engineer is quite generally recognized, but is worthy of emphasis and should receive even more general recognition than it is now accorded. Suppose, for example, that a manufacturer decides to put out a new chassis model. If this model is to be commercially successful and meet the least possible sales resistance it should not depart, at least in most particulars, from practice that is very generally employed and has proved most successful. Consequently it is necessary that both the engineering and sales departments have reliable information on current practice. This information may be possessed by members of the engineering force, but the industry is now so extensive that it is impossible for any engineer or engineering staff to keep up to date or keep record of any considerable proportion of changes being made by other concerns, unless recourse is had to published statistics. This need we endeavor to fill by data published from time to time in AUTOMOTIVE INDUSTRIES, and in particular in the statistical issue.

The information here published enables the engineer to know whether or not his judgment in selecting a given type of construction is confirmed by the judgment of other engineers called upon to make a similar choice. Of course the practice of following a certain procedure simply because a majority of other organizations do the same thing can be carried to excess. If the practice should be universally followed there would be little if any progress or improvement, but the value of the check which a study of statistics makes possible can scarcely be questioned.

Car manufacturers are not the only ones who benefit by the publication of statistics. The parts and accessory maker must follow the trend of competitors' design, as well as study the trend of selections made by the assembler. One of many possible illustrations will serve to prove this statement. In 1914 only 1 per cent of car models used the helical or so-called "spiral" bevel final drive. In 1915 the percentage rose to nearly 10 and in 1916 to over 55. To-day no less than 90 per cent of models employ this type of drive. No axle manufacturer could afford to overlook a trend of this character, yet if he failed in 1915 to equip his plant to supply the demand for the type of drive in question, he might easily have lost much business that would otherwise have been his in the following year.

The Need of Legislation

INCLUDED in this number of AUTOMOTIVE INDUSTRIES is a revision of the registration statistics published in the number of Jan. 13. In the present printing the numbers in several States have been changed and the total of cars and trucks has been

increased from 8,887,572 to 8,932,458. This change was made necessary for the reason that it was not possible to obtain at the time the former count went to press authorized statements from several of the State officials concerned with registrations. It was not the fault of these officials that this information was not available, but the fault of the system established by the State and which the officials are bound to carry out.

The gathering of registration statistics should be a simple task. It appears that all that is necessary is to ask the proper State official for his figures and add them to get the proper total. The task seems so simple that many persons have ventured to accomplish it. Most of these persons have learned that there is much more to it.

In the first place, the system of registration varies in each State. The classification of vehicles is different. In some States the total is not a right total at all. Some classifications must be subtracted, and in some cases classifications that look different must be included. The local meaning of re-registration, for instance, can be ascertained only by studying the law and the practice of the registration office. These factors may easily make a considerable difference in the grand total unless they are intelligently interpreted.

It is unfortunate for the great industry that there is not a more systematic registration of vehicles, and that the laws are not more uniformly enforced. As it is, a count of registrations from month to month does not in any sense indicate the purchase of motor vehicles in a given territory. Rather it indicates the degree of enforcement of the law in that territory. It also is true that a small percentage of motor vehicles escape registration while some motor cars are twice registered when they engage in interstate commerce. These factors probably balance themselves.

The remedy is obvious. It is a uniform registration law. This feature is included in the "Proposed Uniform Vehicle Law" drafted by the Motor Vehicle Conference Committee. If all States would adopt a uniform method of registration and a more uniform method of making accounts, this problem would to a large extent be solved. Another proposed solution is Federal registration. This, perhaps, would be welcome at a proper cost. Such a proposal has been made by the Secretary of the Treasury, but he wishes to charge the automotive vehicle owners $100,000,000 for this service. His plan would be merely to add another registration routine and fee to the present requirements. There already is grumbling among vehicle owners as to registration routine and fees. To add to this would draw a sharp up curve in the line of sales resistance. One can hardly believe that the States will give up the present privilege of taxing motor cars. The revenue is too great to be given up. Many municipalities now tax vehicles half as much as do the States. There must be no more taxes added.

One thing is certain: The automotive industry has within it a great political power. It is the second industry in importance and volume in the country. If this industry should unite in making a reasonable request it could not be denied. The fact that it suffers from bad legislation is its own fault. If the entire industry would place itself whole-heartedly on the side of fair and uniform legislation, it would get its desserts. This is the possibility. The facts are different. There is frequently division in the ranks of the industry as to legislation. Selfishness as to results sometimes crops out before the first score is made. If ever a situation required team work, it is the present situation as to automotive legislation. Forget details for the present and get behind the movement as represented by the Motor Vehicle Conference Committee.

Labor Statistics

THE exact meaning of any particular set of labor statistics is always difficult to determine for two reasons:

First: No clear definition of terms has become general; there is little standardization of terminology in this field of industrial organization, and consequently the statistician may be talking about one thing and his listener be thinking of another.

Secondly: The really vital factors of the labor and industrial relations problem have not yet been reduced to a definite and concrete form which will lend itself to statistical treatment. So many of these fundamental things lie within the minds and the psychological reactions of numerous individuals that in only isolated instances has their very presence been recognized; and in still fewer instances has a thoughtful, intelligent, and sustained effort been put forth to analyze them carefully and to determine what manner of things they actually are.

The chief value of labor statistics that are available—and of any that are likely to be available for many years—is that they do indicate in a general way certain broad facts and tendencies. The fact that there were more than two thousand strikes during the first nine months of 1920 indicates, of course, that an active industrial struggle is taking place, but the frequency of the strikes is no gage whatever as regards the increase or decrease of fundamental industrial unrest. It is merely a gage of the fighting strength of the unions and the employers.

So with figures showing the causes of strikes. These causes were merely the technical point over which the strikes broke in each case, and bear only a distant relation to the underlying causes, which must be traced back into the reactions of the various individuals comprising the employer and employee groups involved.

Present labor statistics, then, are useful as indicators of general trends of certain particular phases of the labor problem. They are of distinct value when put to such a use, and can be profitably studied from that standpoint. It is a mistake, however, to attempt to use them as accurate and detailed guides in any sense of the words.

It is an unfortunate fact that in utilizing any set of labor statistics for purposes of analysis, it is necessary to examine rather carefully the agency by which they were prepared and to understand the basic standards on which the final results were computed.

Concerted Tax Stand Is Essential

Industry as Whole Must Unite on Plan

Congress Sentiment Leans Heavily Toward New Levies on Motor Vehicles

WASHINGTON, Feb. 12.—Thorough inquiry into the attitude of Congressional leaders toward the tax problems of the automotive industry indicates strongly that unless there is a marked change of sentiment, a major portion of Secretary of the Treasury Houston's plan for additional taxes will be accepted without appreciable revision. Sounding out sentiment of Senators and committee leaders of the House revealed an unmistakable tendency to impose a tax which would check purchases of automobiles by individuals of small means. There are legislators who believe that imposition of additional taxes on motor cars would put the brakes on inflation which, they claim, is brought about by hundreds of thousands who buy machines on credit and cannot afford it.

These statements are based on personal opinions of Congressional leaders whose chief object is to raise revenue. Confidence seems to prevail throughout the industry that the recommendations of Secretary Houston for a 50c per horsepower tax would fail because of the inevitable opposition of 8,000,000 car owners. There are Congressmen who admit that such a tax would be inimical to the development of a great industry, but in the next breath say that it is the only logical way to reduce extravagance. With few exceptions, the advocates of this plan concede the essentiality of the automobile, but they claim that if horsepower and gasoline taxes were thus levied they would serve to stabilize general business through deflation. It is believed that the most effective opposition to the Treasury program will come from farming communities, where the effects of the tax would be quickly felt.

Will Act in New Session

The question of taxation will not be taken up until the next session, which probably will be called for March 14. Chairman Fordney of the House Ways and Means Committee advised AUTOMOTIVE INDUSTRIES to-day that tariff legislation would be disposed of and then attention devoted to questions of internal revenue. He stated that his time had been completely taken up with tariff matters so that he has made but little study of the probable effects the adoption of the Houston program would have on the automotive trade.

He declared that representatives of the industry would be allowed sufficient time to present their arguments as to taxation. Chairman Fordney pointed out that the committee was concerned solely with the problem of producing a yield of $5,000,000,000 or $8,000,000,000, a sum which is required to maintain the Federal Government and retire financial obligations during the next fiscal year.

The proposals of Secretary Houston, which would assess the automobile industry $290,000,000 over and above its present contribution to the public revenues, were suggested as a means of bringing more money into the Treasury. Recognizing the economic movement which must inevitably result from the new levy, certain Congressional leaders, stressing the necessity for economy in Governmental and private enterprise, have seized upon it as an effective weapon to force deflation.

Would Make Cars Luxuries

The attitude assumed by these agitators, whose methods of economy border dangerously on parsimony, is reflected in the statement of an influential legislator who said:

"There are thousands of people driving cars to-day who cannot make their payments and are so situated that they may never own the machine outright. This condition only helps inflation when it is deflation we want. If a man finds an automobile an essential utility then he

(Continued on page 434)

$290,000,000 NEW TAX ASKED OF INDUSTRY

These are the tax recommendations made by Secretary Houston which are of special interest to the automotive industry:—

1. Increase of the sales tax from 5 per cent to 10 per cent, which, it is estimated, will make an increase of	$100,000,000
2. A Federal license of cars based on 50 cents per hp.	100,000,000
3. A consumption tax on gasoline at 2 cents per gallon	90,000,000
4. The truck sales tax will be continued at 3 per cent, despite efforts to have it eliminated.......	
New taxes from industry..	$290,000,000

Organizations Will Confer on Program

General Sentiment Favors Sales Tax—N. A. C. C. Formulates Plan of Action

NEW YORK, Feb. 14—Efforts are being made to bring together all branches of the automotive industry for concerted action in opposition to proposals for levying additional Federal taxes on motor vehicles. The impression has gained ground here that there was little probability of serious consideration being given by Congress to the proposals made by Secretary of the Treasury Houston along this line but it is becoming evident that an additional burden will be placed upon the industry unless there is a determined stand against having the automotive industry made the taxation goat.

The tax committee of the National Automobile Chamber of Commerce already has evolved a plan for presentation to the ways and means committee of the House at the special session which probably will be called for March 14. Taxation will be the most important question considered at that session and the hearings on this subject will begin in April. The recommendations of the N. A. C. C. were made after consultation by the committee with financiers and economic experts.

The program outlined calls for relentless handling of the pruning knife in government expenditures and points out ways in which $1,000,000,000 could be saved. The committee contends that if this amount were eliminated from government expenditures, no additional taxation would be necessary, but if further funds were required, they should be obtained by a tax of 1 per cent on all retail sales.

Will Seek Wide Endorsement

This program has not been approved by any other automotive organization although nearly all of them are in favor of some kind of a sales tax. It is the plan of the N. A. C. C., however, to ask every chamber of commerce in the United States to endorse the plan it has formulated or propose a program of its own and every effort will be made to arouse sentiment in favor of a sales tax.

This form of taxation already has been commended by various organizations as well as by prominent bankers and economists. The chief objection to it is that it would be paid by the ultimate consumer and many unscrupulous dealers would use the excuse of a 1 per cent tax to add several times that amount to retail prices. This consideration may weigh

Ford Reorganization Assumes Form

Campbell Probable Choice as Treasurer

Sorenson Mentioned as General Manager—Bankers Discredit Company's Independence

DETROIT, Feb. 15—Shifting of the proposed line-up of the reorganization at the Ford plant puts W. R. Campbell in the office of treasurer. While there is no official confirmation of this report, a statement made to AUTOMOTIVE INDUSTRIES to-day by Campbell, the first he has made since he was asked by Henry Ford to accept the general managership, virtually was an admission he would assume the office of treasurer.

Campbell has been in nominal control at Highland Park for a month and has been at the plant all of every day during the period "simply helping to get things straightened out and in shape for quantity production when the plant starts," as he expressed it.

Although Campbell declined when the position of general manager was offered him, Ford would not accept his refusal and used his persuasive powers to such good effect that Campbell is thought to have given in and Highland Park officials declared it certain he would succeed to that end of F. L. Klingensmith's duties with the office of general manager, also held by Klingensmith, given to some other official.

The new alignment is believed to mean that Ford will act on his first impulse and give the position of general manager to Charles E. Sorensen, now in charge of the Dearborn and River Rouge plants. Some persons still contend Ford will go outside the organization to get a new general manager but the feeling among Highland Park officials is that Sorensen will be named.

Statement Promised Next Week

At any rate, details regarding organization, personnel and plans are promised by Campbell the latter part of next week. Campbell, who is regarded as one of the big men in the industry, has a pleasing personality, is easily approached and accessible when not surrounded by the safeguards of private secretaries and other buffers placed by Ford to ward off newspaper men and others seeking information.

Campbell talked freely although he was reticent regarding his own and the Ford company plans, explaining that his was a delicate position and that it was hardly proper under the circumstances for him to make a statement.

"I have had several propositions put to me," said Campbell, "but I have reached no definite decision. There are several things that must be done before any announcement can be made. Under the circumstances it would hardly be proper for me to make any statement regarding the company, its present operations or future plans. Mine is a rather delicate position and while I have been at Highland Park for the last month I must ask you to wait till definite announcements are ready."

Asked about the report that he would become treasurer rather than general manager, Campbell declared latter position is fraught with many handicaps and difficulties not to be encountered in any other office and added:

Campbell to Make Decision

"But I have not made any decision. I think I can promise you something official the latter part of next week when, if I accept any of the propositions presented, a statement of policies and plans will be in order."

The "relief" shift, declared by Henry Ford in an authorized interview to number 10,000, went to work at Highland Park, Monday, succeeding what he termed a like number who had been at work the two preceding weeks. The present shift will work two weeks and be replaced by the first shift, thereby giving 20,000 employees work two weeks each month pending full resumption.

Reports persist that the alternating shifts aggregate not over 5000 each but no official will make a statement, referring all inquirers to Ford's authorized interview, the only feature of which, aside from the cowless milk theory and the reiterated statement that he does not want borrowed money, was a paragraph outlining the alternating 10,000 shift plan. Officials will not say how the men are employed or the amount of production, if any, but the best information is that the force is working exclusively on parts for dealers rather than building for the assembly line. The Highland Park office is practically cleaned out even to stenographers, clerks and office boys.

Guides also have been eliminated and many Detroit visitors seeking opportunity to go through the big plant are disappointed at their inability to secure admission.

"Why Doesn't Plant Operate?"

Despite Ford's statement that he does not need money, representatives of Eastern financiers continue to visit Detroit and presumably confer with the manufacturer. Local bankers only smile when reference is made to Ford's statement of financial independence. If prodded they ask, "Why doesn't the plant open if 67,000 cars were sold in January as stated in his interview, for at same ratio it will be but few weeks before the supply on hand is exhausted?"

Seiberling Urges Stockholder Support

Says Goodyear Will Show Profit for Year if Financing Is Consummated

NEW YORK, Feb. 15—A special meeting of the stockholders of the Goodyear Tire & Rubber Co. will be held in Akron on March 4 to act on the plan for recapitalization and readjustment of the company's finances. In a letter to stockholders, urging them to attend the meeting, President F. A. Seiberling says:

"The plan for readjusting the debt and capitalization of the company has been approved by the Board of Directors and already many of the largest creditors and holders of a majority of common stock have indicated their assent to it.

"As will be seen from the statement of the company's indebtedness set forth in the plan, the position of the company is exceedingly precarious. Since the annual statement of Oct. 31, 1920, the company's indebtedness (including contingent liabilities, most of which will have to be met) has increased to nearly $66,000,000.

"Notwithstanding the discouragements of the early months of the current fiscal year, it is expected that if the plan is consummated, operations of the recapitalized company for the remainder of the fiscal year will show a considerable margin of profit over all fixed charges, including contemplated sinking funds, and over dividends on prior preference stock."

In the last analysis it will be the merchandise creditors who will determine the fate of the Goodyear company. If they accept the plan a receivership will be avoided, but if they fail to do so, it probably will be inevitable. A letter sent to them by the merchandise creditors' committee says:

Plan Holds Better Promise

"Financial difficulties of Goodyear Tire & Rubber Co. have been generally known for some time. When the merchandise creditors' committee was appointed late in December of last year a receivership was imminent and seemed inevitable, and it has thus far been avoided only with great difficulty. After a thorough canvass of the situation, the committee is advised that the present plan is the only available method of avoiding a receivership, and that a receivership would cause great delay and hold out no promise of as favorable an outcome for the creditors."

It is understood that Goldman, Sachs & Co. and Dillon, Read & Co. have agreed

(Continued on page 433)

McCord Management Taken by Creditors

Schlack to Conduct Affairs of Company Under Committee —Will Extend Claims

DETROIT, Feb. 12—Joseph D. Schlack, former vice-president of the McCord Mfg. Co., has been named general manager to operate the concern by an advisory committee of creditors named yesterday. L. M. Hamlin, present secretary and treasurer of the company, will continue in that capacity. President A. C. McCord and his brother will retain membership on the Board of Directors, but will relinquish their salaries and will have no voice in the management of the company, other than as board members acting under instructions of the advisory committee.

Approximately 100 merchandise creditors and representatives of a half dozen banks attended the meeting yesterday and subscribed to the agreement submitted by a committee of bankers and larger creditors, which contemplates operation of the concern pending adjustment of financial difficulties. The agreement provides that all claims of the company will be extended six months with privilege of renewal for a similar period, all claimants to be given notes bearing interest from the date the agreement becomes effective. The period of extension is a matter entirely in the control of the advisory committee, which has authority at any time and for any reason to declare a claim due.

The committee named is as follows:

L. H. Jones, Detroit Copper & Brass Co.; A. B. Seelig, Michigan Copper & Brass Co.; A. White, Pratt & Letchworth, Montreal; C. H. Harris, of C. H. Harris, Inc., New York; H. S. Hayden, of Hayden-Westcott Lumber Co., representing the merchandise creditors, and Ralph Van Vechten, Continental and Commercial Bank, Chicago; F. G. Smith, First & Old National Bank, Detroit; Walter Dunham, Dime Savings Bank; Averill Tilden, Merrill Cox Co., Chicago, and John Fletcher, Fort Dearborn National Bank, Chicago, representing the banking creditors, with Fletcher as chairman of the committee.

Officers Under Committee

Under the agreement officers, directors and stockholders will abide by the instructions of the advisory committee, and will perform any duties or execute any orders issued by the committee. The McCord family interests, which own 65,000 shares of no par common stock, under terms of the agreement, will transfer that stock to trustees named by the advisory committee to assure the committee voting power. Hamlin assumes the position of comptroller for the committee, the agreement stipulating that the concern be operated pending readjustment under active control of a general manager and comptroller named by the committee.

The bank creditors, under the agreement, will furnish capital sufficient to operate the plants of the company, prorating the advances among the banks, which new loans, together with payrolls and new material purchases, will constitute a prior lien against the company. The banking indebtedness is unsecured save by the endorsements of the McCords.

While all creditors represented yesterday signed the agreement, their claims have not been adjusted to market values, and that matter under the agreement is left in the hands of the advisory committee. In a statement filed by accountants approximately 20 per cent was deducted from the merchandise inventories to represent shrinkage in market values, and the committee will take similar action in arriving at credit value of claims of merchandise creditors. It was brought out at the meeting that the West Pullman unit of the company, which makes railway supplies, was the one big handicap to successful operation, that plant losing approximately a half million dollars last year, while the other plants of the company showed fair profits.

Declare Conditions Hopeful

The drain caused by the West Pullman losses, together with dividends paid by the company, are held to be responsible for conditions, which, Chairman Fletcher declared, were found to be such ten days ago as to make quick action imperative. Fletcher said, however, the company's condition was not such as to cause serious concern if co-operation of the creditors could be secured, and added that the McCords had been in every way fair throughout all proceedings and very willing to abide by any suggestion the bankers made looking to a fair and equitable adjustment of difficulties.

It was announced by Fletcher that the West Pullman plant now is closed, and that steps looking to the disposal of that unit would be taken immediately. The Racine unit, which builds bodies, and the radiator and axle plants in Detroit are in good condition and have shown profits right along, Fletcher said.

The company's banking and merchandise liabilities amount to approximately $5,000,000, divided about evenly between banks and manufacturers. All of the creditors showed willingness throughout the meeting to co-operate in any way to bring about a fair adjustment, and the feeling was apparent that the McCords were taking the only fair and reasonable course for protecting all concerned.

RECEIVER TAKES SUBSIDIARY

SANDUSKY, OHIO, Feb. 14—H. R. Greenlee, receiver for the Erie Tire & Rubber Co., has been appointed receiver for the Sandusky Land & Building Co., to which the tire company advanced out of its treasury more than $300,000. The receiver was given authority by the court to complete two large apartment houses started by the land company. The tire company owns 95 per cent of the stock of the building company.

Fort Wayne Creditors Ask Receivership

Charge Heavy Shrinkage in Assets of Company — File $110,000 in Claims

FORT WAYNE, IND., Feb. 14—The reorganization of the Fort Wayne Tire & Rubber Co., which has been proceeding for several months after the election of new directors and the elimination of contracts held by the promoters who formed the company, has received a setback through the filing of three suits on account, demanding $110,000 and asking for the appointment of a receiver for the company.

The plaintiffs and the amounts of their claims are as follows. Jenckes Spinning Co., $60,000; Fred Stern & Co., $48,000; Majestic Tire & Rubber Co., $3,000. The complaints recite the history of the company and declare that after the recent reorganization was completed the creditors agreed to an extension of credit until Jan. 31 to permit the new management to raise $250,000 among the stockholders to meet the company's immediate obligations.

The complaint states that so far this has been unsuccessful. The complaint further states that a recent audit showed $200,000 in fixed assets, real estate, etc., $200,000 in material, and $45,000 in accounts receivable, making total assets of $445,000. The liabilities were then established at $275,000.

The petitioners set out that the accounts receivable shown in this audit are uncollectable, that the value of the plant and real estate has decreased through lack of a market and is worth only $100,000, and that the material on hand has decreased to a total value of $125,000, making the total assets at present but $225,000. The charge is also made in the complaint that the new management, in its efforts to obtain funds, sold the company's products below cost, and by introducing the "flying squadron" method in manufacturing, produced tires at a cost in excess of their value on the market.

FINANCE COMPANY FORMED

MILWAUKEE, Feb. 14—The Automotive Finance Corp. of Milwaukee is the name of a new corporation organized under the laws of Wisconsin to handle motor car, truck and tractor securities, notes, etc. The initial capitalization consists of $100,000 preferred stock and 500 shares of common stock without par value. The incorporators are T. J. Maher, William J. Sarres and Leonard M. Broenen, Milwaukee.

NEDOMA-NAJDER CHANGES NAME

NEW YORK, Feb. 14—The name of the Nedoma-Najder Motor Syndicate has been changed to the Nedoma-Najder Patent Syndicate, and new offices have been opened at 299 Broadway.

Extension on Claims Sought for Willys

Committee Outlines Advantage of Co-operation — File Claims Against Chrysler Plant

NEW YORK, Feb. 15—Creditors of the Willys Corp. have been asked for an extension on their claims until May 1. A letter outlining the position of the company and urging that the extension be granted has been sent out by the committee headed by Theodore Beran of the General Electric Co., which represents merchandise and construction creditors. This committee will co-operate with the bankers' committee, which has taken charge of the company's finances.

The letter states that the company is solvent and has very substantial assets in excess of liabilities. The abnormal industrial conditions which have prevailed for the last few months have made it impossible to arrange new financing. The committee recommends that claims be deposited with the Bankers Trust Co., which is the official depository.

When a sufficient number of claims have been deposited to make the plan effective, it is proposed to give a three months' extension in which to pay the indebtedness and where this indebtedness is represented by acceptances the creditors are expected to authorize the committee to take new acceptances maturing May 1. The company has informed the committee that it hopes to be in a position before that time to make a definite settlement of claims with creditors. The proposed agreement provides that no further extension shall be given and no settlement made at less than the amount of claims in cash without first submitting the offer to the creditors.

A considerable number of the creditors claim the right to file mechanics' liens against the plant now nearing completion at Elizabeth, N. J. The committee has retained lawyers to file liens on behalf of creditors who deposit their claims. When these claims are filed, the committee may agree with the company to extend the time for the enforcement of them beyond May 1.

Unwise to Force Claims Now

The letter says the committee is convinced it would be most unwise to attempt to force claims at this time. Any attempt by one creditor to obtain a preference would necessitate action by the other creditors. This, in the opinion of the committee, would have a very disastrous effect upon the value of the assets and would be most harmful to the industry in general.

The letter states that the committee will examine the assets and commit itself to no definite policy until the facts have been studied, but it has been advised that the creditors ought to receive payment in a reasonably short time.

WILLYS CORPORATION BALANCE SHEET SHOWS TOTAL ASSETS OF $53,694,153

NEW YORK, Feb. 15—Following is the balance sheet of the Willys Corp. as of Nov. 30, 1920:

CURRENT ASSETS			
Cash		$2,330,595	
Securities of other companies, including 739,866 shares of the Willys-Overland Co., valued at $8 per share		10,680,321	
Notes and accounts receivable		4,281,827	
Inventories		8,572,470	
Miscellaneous		301,024	
			$26,166,237
CONTINGENT ASSETS			
Equity in book value of securities at present market value		$11,059,279	
Good will and patents		890,134	
Redemption fund, including preferred stock, land, bldgs. and equipment	$18,279,080		
Less reserve for depreciation	2,700,577		
		15,578,503	
			27,527,916
Total assets			$53,694,153
CURRENT LIABILITIES			
Accounts payable		$2,958,445	
Notes payable		11,450,000	
Accrued accounts payable		234,152	
Dividends payable		4,075	
Miscellaneous		23,848	
			14,670,520
DEFERRED LIABILITIES			
Scrip dividend on first preferred stock		$298,000	
Reserve for taxes		347,294	
Premiums on preferred stock		23,290	
Capital stock outstanding, (first and second preferred and common)		38,355,049	
			$39,023,633
Total liabilities			$53,694,153

Reynolds Receiver Makes 20 Cent Offer

MOUNT CLEMENS, MICH., Feb. 15—An offer to pay all creditors of the Reynolds Motor Truck Co. 20 cents on the dollar of their claims has been submitted to them by Charles J. Reimold, the receiver appointed in Superior Court. The receiver has notified all creditors to file their claims within 90 days and that the assets will be distributed as soon as practicable after that date without reference to claims not proved when dividends are made. The creditors' committee headed by Harry S. Graves, which sought unsuccessfully to have a co-receiver named, has not yet decided upon the advisability of petitioning the company into bankruptcy.

BEARINGS COMPANY RESUMES

WORCESTER, MASS., Feb. 15—Receivers for the Massachusetts Oilless Bearings Co. have resumed operations in the wood bearings department and are rapidly completing uncancelled orders and taking on new work. Their operations have been interrupted because the safe containing the records of the company has not yet been recovered from the wreckage of the Knowles building in which their offices were located and which was destroyed by fire on Jan. 19.

Revere Seeks Funds To Continue Plant

LOGANSPORT, IND., Feb. 14 — Stockholders of the Revere Motors Corp. have elected a new board of directors to devise ways and means to place the company on a solvent basis by the floating of a bond issue. The company now is in the hands of a receiver in a friendly suit brought by U. S. Hoffman and Charles Hanna, stockholders.

The new directors elected are C. C. Bishop, Charles Young, A. L. Jones, M. L. Fansler, A. A. Seagraves, Edward W. Kelly and E. F. Metzger. They propose to issue first mortgage bonds to the amount of $250,000. The indebtedness of the company at present is given as $217,000, and several suits are pending against it for breach of contract. About 75 per cent of the stockholders are residents of Logansport. It is believed that if a bond issue can be floated the company will be re-established on a firm basis.

TO PAY PATHFINDER CLAIMS

FRANKFORT, IND., Feb. 15—Creditors of the Pathfinder Motor Co. of America have been notified by Harry C. Sheridan, referee in bankruptcy, that a final dividend of approximately 20 per cent will be paid them on Feb. 24.

Packard Under Way With 1000 Employees

Non-union Workers Replace Strikers in Body Plant—Sales Show Increase

DETROIT, Feb. 14—Approximately 1000 employees among those laid off at the Packard plant, Jan. 30, returned to work Friday. No discrimination is being made as to married men or men with dependents, employment officials simply notifying the men needed in various departments to again get the plant under way.

The men on strike in the painting and trimming room in the body department still are out, but sufficient non-union workmen have signed up to assure steady operation of that department permitting of resumption in other divisions. Packard officials also said many men who had been members of the union had given up their cards and signified their desire to get back on the job.

Announcement of the reopening of the plant was made in the following formal notice: "Packard Motor Car Co., simultaneously with declaration of the regular dividend of 1¾ per cent to preferred stockholders, announces to employees that increases in sales and great improvement in spring business is responsible for a decision to put on 1000 employees immediately."

About 3000 men were laid off when the plant went down, and while Vice-President Roberts expressed hope of resumption in ten days, employees were informed that the shut-down might last thirty days. The action was taken, Roberts said, to permit of balancing inventories. The announcement to-day disposes of rumors that the March dividend would be passed.

Sinclair to Sell Its Motorcycle Business

NEW YORK, Feb. 14—Sidney S. Meyers, general counsel of the Motor and Accessory Manufacturers Association, has been informed by Charles Margerum, trustee in bankruptcy for the Sinclair Motors Corp., that an agreement has been entered into with a firm of New York attorneys, under which the assets of the company applying to the manufacture of motorcycles, together with the property in the Springfield plant, consisting of equipment and machinery, will be held intact until April 21 to permit the attorneys to submit an offer for the purchase of the assets or settlement with the creditors. The terms of this offer have not been made definitely, but it can be stated an effort is being made to interest capital in the reorganization of the motorcycle business.

Margerum stated that this offer, together with the funds which will come in from the sale to the Winther Motor Truck Co. of a Government contract for the manufacture of seventy-five Militor trucks, will be sufficient to permit payment of about 30 cents cash on the dollar to the Sinclair creditors and 70 cents on the dollar in second preferred stock in a new corporation which will be formed to take over the motorcycle business. Sinclair will get $90,000 for the transfer of the truck contract together with the dies, tools and materials owned by the company.

Margerum has been authorized to effect a compromise with the Knox Motors Corp. by an entry of judgment for the plaintiff in seven replevin suits pending in Superior Court. There are now on hand sufficient funds to cover the claims of workmen for wages for the week ending Oct. 9.

Oneida Official Finds Truck Outlook Better

GREEN BAY, WIS., Feb. 14—On his return from a month's business trip through the Pacific Coast region, Lafayette Markle, president and general manager of the Oneida Motor Truck Co., Green Bay, Wis., reported a most encouraging condition in respect to the motor truck market. Markle and his assistant, J. E. Johnston, established Oneida dealers in a number of the principal cities of California.

"California is one of the best fields in the world for motor truck manufacturers," said Markle. "It is an all-year-round market. The business men are enthusiastic over the truck. Fine roads and climate make it possible to use the commercial as well as passenger car twelve months in the year. In one instance motor bus lines put out of business a 50-mile railroad running south out of San Francisco. Figures compiled from sales sources show that the average sale of trucks in southern California alone is between 550 and 600 trucks every month. Organization of new bus line companies, enlarged operations in power development, road construction and general freight and passenger traffic call for a large number of new trucks.

It was announced upon Markle's return that the Oneida company will soon place in quantity production a new type of light truck designed for the needs of farmers and business men. Up to this time the Oneida truck has been built in sizes from 2½ tons upwards.

CREDITORS SUE SANDOW

BOSTON, Feb. 11—A creditors' petition in bankruptcy was filed to-day in the United States District Court against the Sandow Motor Truck Co. of New England. with claims against the company of $61,642. Creditors are the Commercial Finance Corporation of Boston with a claim of $39 986, and the Detroit Auto Radiator Co. of Boston with a claim of $16. The petition alleges that at a special meeting of stockholders held Feb. 7 it was voted that the treasurer of the company, S. D. Griffiths. express in writing the company's inability to pay its debts and its willingness to be adjudged bankrupt.

Pierce-Arrow Ready to Resume Schedule

Factories Completely Reorganized to Manufacture New Models—Will Employ 5000

BUFFALO, Feb. 11—Completion of the vast amount of work preliminary to the establishment of regular production schedules for its new passenger cars and truck models was announced yesterday by the Pierce-Arrow Motor Car Co. Both passenger cars and trucks have been produced in a limited quantity during the last few months, the work of preparation for normal production progressing simultaneously.

"Few appreciate the enormous amount of detailed planning and physical work necessary to rearrange a big factory, install new machinery and produce new tools, dies, jigs, templates and other essentials required when new motor car and motor truck models are launched," said George W. Mixer, president of the company.

"This work requires a large force of men, and for that reason a large payroll was maintained by the factory during the last few months when other plants have found it necessary to curtail or to shut down."

The task of preparation having been accomplished, says Colonel Mixer, the company has effected a readjustment of its factory forces. About 500 who have been engaged in work of preparation are being laid off, but the bulk of the factory force, numbering 5000 workers, will continue regular production.

Interlocking Creditors Request Liquidation

AKRON, Feb. 11—Complaints of creditors of the Interlocking Cord Tire Co. that the affairs of the company were hopelessly muddled and asking for the appointment of a permanent receiver that the affairs of the company may be liquidated at once, will be heard by Judge Wright on Feb. 28. He has instructed that a meeting of the company's 5000 stockholders be held before that time to consider the situation.

Through this action the creditors and 400 stockholders who originally petitioned for the appointment of a receiver, practically abandon all plans for a reorganization of the company. The creditors asking the liquidation of the company hold claims aggregating $120,000. The officers of the company are under indictment for alleged violation of the Ohio blue sky laws.

FORD-CAMBRIDGE REOPENS

BOSTON, Feb. 11—Operations have been resumed in all departments of the big Ford Motor Co. assembling plant at Cambridge. The plant has been closed following the closing of the parent factory in Detroit.

Iowa Stages Show to Break Depression

Gradual Liquidation of Crops Expected to Start Buying—Many Cars Warehoused

SIOUX CITY, IOWA, Feb. 14—Automobile, truck, tractor and accessory dealers opened today their first show in four years—a show which is expected to revive, in a measure at least, a business which has been virtually dead since Ford cut his prices last September. In fact, sales here have been all but negligible since April, 1920, when the tightening of bank credits began, but the Ford price-cut proved the cap-sheaf of a steadily rising wall of sales resistance, which has reduced country dealers to the state of garagemen, storekeepers, bankers or whatever they were before they undertook automobile agencies, and which has forced dealers in the city to live on the profits of 1919 and early 1920.

It seems incredible that this richest agricultural center of the country, marketing point for a large area of wonderfully fertile lands in Iowa, Nebraska and South Dakota, could have suffered such a business depression, but it has. The trouble lies in the sharp decline of farm produce prices, weakening the farmer's buying power and creating a resentment against the slower trend downward of other prices which has virtually taken the farmer out of the market, and in the withdrawal from this territory of millions of dollars which the overprosperous farmers, merchants and wage-earners—and even some of the bankers—invested during the boom period in stocks which are now worthless, or nearly so.

There were some local promotions which absorbed huge sums of local capital—for instance, a packing plant which is now in receiver's hands—but much of the money invested in securities whose promoters promised big dividends has gone East or West with the promoters, who lost little time in seeking climes which would be healthier—for them. The money is gone, $200,000,000 from Iowa alone, it is said here, and another harvest will have to be marketed before anything like normal conditions can prevail.

Bank Loans Due March 1

There is prospect of some improvement in the situation after March 1, when banks generally are calling farmers' loans long overdue, thus forcing the agricultural community to disgorge last year's and even some of the 1919 crops stubbornly held in hope of higher prices. The crop liquidation movement is now under way, proceeding about as fast as the elevator men can handle it, and it is on this break in the tight money wall that the automotive men are pinning their faith—and holding a show to exhibit their faith to the community.

Dealers here do not see any possibility of big business this year and this is why: First, they must move a considerable stock of goods in warehouse, a stock which some manufacturers forced into the territory even after the then slow sales came to a complete halt in September. Then they must combat an organized movement of farmers not to buy—anything. Farmers are organizing to use each other's machinery in turn, which necessitates the most vigorous sort of sales effort by the tractor and implement men.

Crops Fail to Pay Rent

The farm situation is something like this: The renter, who depends on his crops to pay the landowner, got a price so low, if he sold at all, that he couldn't pay his rent or his grocery or garage bill or his loan at the bank on machinery or seed. The farm-owner, in many cases, bought stock which is paying no return or took part in the frenzied land speculation which inflated values from $200 to $900 an acre.

The farmer borrowed from the bank to buy the stock or the land, giving notes on his outright holdings. He hasn't paid the bank either, in many cases because he refused to raise the money by selling at forty cents corn which he planned to sell at $1.40 when he borrowed and spent the money he was going to get for his crops. The result is no money to loan in the country banks or in the city banks to which they are tributary, and the final result of all this is business stagnation.

But big business men here, including some of the automobile men, are counting on the farmer to come back into the market when he sees the 1921 crop breaking through the ground. With the banks pressing him to take up his notes, it is believed that the natural inclination to sell the old crop when the new one begins to grow will be in evidence, that the farmer will accept his loss, forget some of his resentment and buy some of the things he needs and wants.

In the used-car field there is no market and dealers have some stocks. Low-priced cars, like used cars, are in low demand, too, because it was the renters largely who bought them. And the higher priced car field has to face the opposition of bankers who have repeatedly threatened to force payment on a farmer's notes when the word got around that the farmer was going to buy a car. It has happened even in cases where a farmer worth $100,000 owed the bank only $20,000, but the bank needed the money, and the farmer, who would have sold $2,000 or $3,000 worth of produce, even at a sacrifice, refused to let go $20,000 worth—still hoping for higher prices—so he bought no car.

Potential Trade Large

However, there are in this territory thousands of rich farmers, elevator men, live-stock men and merchants, men who are rich in the huge profits of the war period, despite their losses of the past ten months. Dealers in cars, trucks, tractors and accessories are going to sell to them and get a fair volume of business until the next harvest sets this country on its feet again.

Favorable Influences Help Trade in South

Atlanta Reserve Bank Finds Return to Stable Conditions Well Under Way

ATLANTA, Feb. 12—The most recent report of the Federal Reserve Bank of Atlanta for the Sixth Reserve District, which comprises most of the Southeastern area, indicates a gradual improvement in virtually all lines of business throughout the district, officials of the bank declaring that this fact may be taken as evidence that the period of depression and readjustment has passed and that the return to normal, or what might be better termed a more stabilized condition, is under way.

Numerous manufacturing plants throughout the Southeast that have been shut down for several weeks, some of them for months, have resumed operations since the first of the year and this, too, is indisputable evidence that business is improving. The reopening of numerous textile mills in the South will undoubtedly have a favorable effect on the cotton market, and it is already noted that the price of the South's greatest product is beginning to climb.

This, in turn, will have its effect on the automobile industry in this section and will greatly stimulate sales when cotton prices have climbed back to a reasonable figure.

Atlanta dealers continue to enjoy what can be termed a fair volume of business. As compared with November and December of 1920, the total volume of January business among Atlanta dealers was very good, though, of course, considerably below normal. The increase in business experienced during January is taken by the dealers to mean better things to come and continual improvement from now on.

Spring Weather Helps Move Milwaukee Cars

MILWAUKEE, Feb. 15—The glutted condition of the used car market is gradually being overcome by the vigorous efforts of dealers, which have been supported by a natural advantage of spring-like weather, especially during the last week to ten days. Attention, of course, is also being given to merchandising new cars, but primary consideration is directed at used vehicles to prevent any further accumulation, inasmuch as from 70 to 80 per cent of purchases of new cars are involving trade-ins.

Climatic conditions all winter have been wholly unusual in being extremely mild, and if this condition continues until spring arrives by the calendar, it is felt that the usual seasonable demand will be not only advanced considerably but assume excellent proportions. When people talk of "spring fever" in the middle of February, the psychological attitude necessarily is advantageous to the trade.

Italian Factories Increase Exports

Fiat Creates Production Record in December — Communist Movement Loses Ground

TURIN, Feb. 5 (*Special Correspondence*)—All trace of the Communist movement of last September in the Italian automobile factories has now disappeared, and work is being carried out in every case under the old management and with more vigor than ever. The Government decree fixing the appointment of joint shop committees does not appear to have made any appreciable change.

The committees exist and are recognized by the employers, but they have not been the means of giving the workers any real power in the control of the works. The present arrangement is only temporary, and a more permanent scheme is being prepared. The claims of the extremists for power to decide the condition of contracts, to make purchases, and to determine the rates of wages have all been abandoned.

General conditions in the industry appear to be much more favorable than in other European countries, which is doubtless owing to the fact that Italy has a substantial export business and is able to hold foreign markets at the present by reason of her rate of exchange. At the Fiat factory, which is the biggest in Europe, it is declared that the month of December showed a record output for the year, 70 cars per day being maintained for the entire month. Probably 85 per cent of these were sent abroad.

Fiat is pushing forward work on its new 5-story factory at Lingotto, which was begun during the war. This is by far the biggest factory devoted exclusively to automobile production in Europe. At the present time only the forges, forming an addition to this factory, and the body shops are in operation, all other work being done in the old factory.

Trucks and Tractors Dull

Fiat is working principally on passenger cars, for the truck market is very dull and there is also a slackened demand for agricultural tractors.

A few months ago the Ansaldo company, one of the biggest general engineering concerns in Italy, produced a light 4-cylinder overhead valve job, designed for economical production. This is being built in Turin, and although a few have been put on the market, there are no indications that Ansaldo is going to spread to any extent in this business. The intentions of the company are not known, but it would appear that the present is not considered a suitable time for coming into competition with existing and well established firms. The Spa company, which is specializing on two high-class models, is under the financial control of Ansaldo.

Lancia is continuing work on his 4-cylinder model and is maintaining his output. A year ago he exhibited a high-class 12-cylinder job, and promised deliveries for the middle or fall of 1920. Changed conditions, however, have decided him to hold back the 12, for the market for this class of car has shrunk and production costs have considerably increased. Isotta-Fraschini has got into production on the high-class 8-cylinder in line exhibited at the recent show.

Maxwell Merger Plan Opposed in New Suit

WILMINGTON, DEL., Feb. 16—Charles J. True, a resident of Illinois and owner of 400 shares of the first preferred stock of the Maxwell Motor Co., has filed a petition in United States Court here for the appointment of a receiver and an injunction against the consolidation of the company with the Chalmers Motor Co. A subpoena was issued returnable March 7.

Minority Action Expected

NEW YORK, Feb. 16—Filing of a minority stockholders' suit against the Maxwell company occasioned little surprise here because it had been expected for several weeks that such action would be taken. A considerable amount of the stock has not been deposited under the reorganization plan. It is not expected that the courts will grant the petition, for it would militate seriously against the success of the merger.

W. R. Wilson May Head Maxwell Combination

NEW YORK, Feb. 16—Dwight E. Lee, general manager of the Motor Products Corp., left for the East to-day. One of the purposes of his trip is to confer with the Maxwell-Chalmers management committee on the question of taking charge of production for the corporation. The subject has been broached to him before, but it is understood he is not eager to accept.

Another man who has been suggested for the position is W. R. Wilson of the Irving National Bank, New York, who formerly was connected with Dodge Bros.

While reorganization of the personnel of the Maxwell-Chalmers combination is being given serious consideration by Walter P. Chrysler, chairman of the management committee, no announcements have been made, and it is understood here several weeks may elapse before a selection is made.

Franklin Production Back to 100 Per Cent

SYRACUSE, Feb. 14—H. H. Franklin Mfg. Co. resumed production at 100 per cent capacity on Feb. 10, employing approximately 300 persons. Orders for January delivery exceeded January production by 15 per cent, and on Feb. 1 the company had on hand 426 unfilled orders. Price increases of from $100 to $150 will become effective March 1.

Dunlop Deprecates Stability Attacks

Takes Steps to Protect Interests in American Company—To Raise New Funds

(*By cable to* AUTOMOTIVE INDUSTRIES)

LONDON, Feb. 14—A meeting of the stockholders of the Dunlop Rubber Co. yesterday was largely attended. There was much interest in the proceedings, and an amicable feeling prevailed at the end. Irish stockholders insisted on the protection of their interests but they were satisfied with the promise of F. A. Szarvasy, temporary chairman of the board, that the assets were more than sufficient at the present time to meet liabilities and to pay all stockholders twenty shillings on the pound.

Szarvasy deprecated reports that the company was in a serious position. He said some of the recent offering of 3,000,000 pounds sterling in stock was subscribed for by persons who were without adequate resources and who had to realize on their purchases indiscriminately. It is the apparent intention to raise 5,000,000 or 6,000,000 pounds by the sale of debentures.

Stockholders were informed proposals for financing the American Dunlop Co. could not be carried through, and it was decided to remit the sum of 806,000 pounds to avert a receivership and give time for further negotiations. A committee of the directors went to America to arrange a bond issue of $6,000,000 and safeguard the position in America, but further working capital is required. It was the original intention to issue bonds for $12,000,000 or $14,000,000 to redeem bonds and provide working capital.

Reports indicate that the American business ought to prove a big success. If the parent company had not taken the steps it did, the alternative would be to abandon interest in it and to risk the acquisition of the United States factory by rivals with the right to use the Dunlop name. The meeting authorized the directors to guarantee payment of bonds and to increase the preference share interest.

The press indorses the action taken as the best way out of an uncomfortable position, and characterizes it as a personal triumph for the tact and business ability of Szarvasy.

RAPID RIM PETITION FILED

FORT WAYNE, IND., Feb. 14—Petition has been filed in the local Federal court before Clerk T. J. Logan to have the Rapid Rim Co., of Huntington, Ind., declared bankrupt. The petition was filed by Albert L. Heinns, Henry F. Meyers and J. Archie Borland, who was formerly president of the company. It is declared in the petition that the company owes its creditors more than $100,000. A large number of Fort Wayne firms are among the creditors of the company.

Army Truck Dumping Opposed in Senate

Will Seek Allocation to States for Highway Purposes Under New Bills

WASHINGTON, Feb. 15—Strong opposition has developed in the Senate to the plan sponsored by Representative Anthony of Kansas to dump surplus army trucks, passenger cars and tractors on the open market, to such an extent that it is quite likely that the tentative legislation will fail. Three Senators have introduced separate measures having for their express purpose the transfer of this material to the highway organizations of the different states.

Senators Ball, Delaware; Norris, Nebraska, and Dial of South Carolina, have submitted bills which incorporate all the features of the Reavis bill introduced recently in the House to authorize the transfer of all surplus motorized equipment to the Bureau of Roads and the various States. Proponents of this legislation have obtained nation-wide endorsement from State officials. The Norris measure is offered as an amendment to the Army appropriation bill.

It is said that Senator Ball has undertaken a study of the situation, and, as a result, will convince the Senate of the economic advantages to be derived from transfer to various States rather than open sales. Because of the evident desire of numerous Senators to support the transfer legislation, it is probable that the Anthony rider will be eliminated before the Army bill is reported to the Senate.

The fact that three Senators representing different political parties and widely separated sections introduced three measures for the transfer of the surplus material indicates that the interest in the proposed sale of motorized equipment is national in scope. The Army appropriation bill as it passed the House and is now pending in the Senate Finance committee, directed the War Department to sell 10,000 trucks and 1000 automobiles.

Would Sell 2000 Tractors

The fortifications appropriation bill reported out to the House by Representative Slemp of Virginia, carried a paragraph authorizing the expenditure of $600,000 for alteration and maintenance of mobile artillery, including the purchase and manufacture of tools, machinery and materials and expenses of mechanics engaged in the work. But the sub-committee inserted a proviso which would make it impossible to spend this sum unless the 2000 tractors were sold. As new legislation it will be subject to a point of order when under consideration in the House late this week and may be eliminated.

Senate leaders advised AUTOMOTIVE INDUSTRIES to-day that the pressure of other legislation would undoubtedly block the consideration of the Army appropriation bill at this session. Though the President-elect has requested that the decks be cleared for taxation measures at the new Congress, it is unlikely that pending measures can be disposed of before adjournment March 4. It is learned that majority leaders are desirous of having the Army bill last on the calendar, if possible, because of the signs of a filibuster in event an effort is made to continue the House plans for selling motorized equipment.

Hicks-Parrett Tractor, Formed by New Merger

CHICAGO, Feb. 16—The Parrett Tractor Co. (wheel type) and the Hicks Tractor Co. (crawler type) have been merged into the Hicks-Parrett Tractor Co., the merger being effected so that the two types of tractors to meet differing local conditions could be manufactured in the one factory.

The company is capitalized for $3,500,000 and occupies 147,000 ft. of floor space at its factory here. The officers of the new company are Vincent Bendix, president; Robert Barbour, vice-president; George A. Gibson, vice-president and general manager; R. P. Hicks, vice-president in charge of engineering; J. E. Tracy, vice-president; Russell A. Reed, vice-president and head of the export department; Herbert L. Scharlach, treasurer; Walter J. Buettner, secretary.

The directors include Barbour, Scharlach, Tracy, Hicks, Gibson, Bendix, Warren Barbour, Henry A. Rudkin and B. A. Tomkins. The company also manufactures a line of motor trucks.

Harvester Increases Akron Truck Schedule

AKRON, Feb. 14—The Akron motor truck works of the International Harvester Co. this week started on a production basis of 150 motor trucks weekly. One order of 500 trucks for foreign shipment will be completed within the next two weeks. The company is also operating on a basis of production of 6000 thresher machine engines this year, and contemplates increasing its factory forces materially in March.

NAPOLEON ELECTS OFFICERS

TRAVERSE CITY, MICH., Feb. 11—Stockholders of the Napoleon Motors Co. at the annual meeting here elected the following board of directors: W. G. Rath, C. D. Peet, Frank Trude. E. G Arntz, W. J. Chase, L. W. Smith and Frank Brooker. Officers remain as last year except that W. G. Rath was elected secretary-treasurer to succeed Frank Trude, and C. D. Peet succeeded W. G. Rath as general manager.

The business situation of the company was considered satisfactory with current assets more than five times current liabilities. The directors announced the payment of a 10 per cent dividend on all outstanding common stock; 8 per cent in stock and 2 per cent in cash scrip, payable Aug. 31.

Protest Increases in New York Fees

N. A. C. C. and Dealers' and Truckers' Organizations to Combat Proposed Legislation

NEW YORK, Feb. 14—At a meeting called by the Motor Truck Association of America here today at the Café Boulevard and attended by representatives of the N. A. C. C., the Commercial Truckers' Association of America, the Long Island Automobile Club, the New York State Association of Automobile Clubs and the New York Dealers' Association, besides several large individual users of trucks, such as the U. S. Trucking Corp., it was decided to form a joint legislative committee of all the associations represented and others to carry direct to Governor Miller a protest against any increase in the license fees for either motor trucks or passenger cars.

Evidence presented at the meeting seems to show that the total income from license fees in the State of New York last year totaled approximately $9,000,000, whereas the cost of road maintenance and construction amounted to only $7,500,000.

Aside from all other economic considerations which should be taken into account in regard to both passenger cars and motor trucks, the legislative committee will claim that there is no justification in raising license fees at this particularly critical period in our reconstruction, so long as the total license income exceeds the cost of road maintenance and reconstruction.

The following statement has been prepared by the Merchant Truckmen's Bureau with reference to the proposed legislation:

"The move to tax the heavy motor truck from State roads is out of line with the general policy of present-day transportation.

"The motor truck has brought outlying communities into closer touch with the metropolitan district, has served as a communicating link between cities and, under the stress of emergency, has taken up the long haul of railroads when their services, because of labor difficulty or congestion, became inadequate.

Trucks Cut Cost of Living

"The motor truck brings perishable commodities to the cities in large quantities, and, when green vegetables were held at prohibitive prices by commission merchants, it was the motor truck which went out into the country and brought in produce, forcing concessions in prices.

"The motor truck has become a part of our transportation system because it has demonstrated its ability to do certain work more economically and expeditiously than can be done any other way.

"Instead of discouraging the use of motor trucks for the preservation of roads, the motor truck should be recognized as a national necessity—a part of our transportation."

Good Roads Congress Urges Speeding Work

Exemplifies Need of Wise Expenditures in Year's Program —Available Funds Large

CHICAGO, Feb. 14—Scarcely had the doors of the Coliseum closed on the national automobile show than they swung open on the eleventh American Good Roads Congress, the eighteenth annual convention of the American Road Builders' Association and the twelfth National Good Roads Show. Some dealers who attended the automobile exhibit remained over this week, so intimate is the relationship between good roads and the industry, and the Chicago Automobile Trade Association interested itself in helping to entertain the visiting good roads delegates.

The question which confronts the road builder, it was shown from the discussions, is not where to get the money for improvements but how wisely he can spend it. It is realized that with the changed traffic conditions greater study should be given to the character of roads to be built and the kind of maintenance to be given those highways already constructed. There is a feeling that maintenance should be kept at 100 per cent, regardless of mileage contemplated.

Immediate construction on roadwork was urged. The discussion of sub-grades was one of the most important on the program.

"The crying need, as far as that need can be seen at the present time," said H. G. Shirley, secretary of the Federal Highway Council, "is to build a road that will have a uniform strength, so as to carry a specific load over its entire length without danger to its structure. We all know that on gravel soils with a high bearing power a thick surfacing will not be required, whereas on soil consisting of clay a very much thicker surfacing will be required to carry the same load certain seasons of the year. Why, then, should we persist in laying the same thickness of surfacing over the clay soils that we lay over gravel and other more stable materials? Millions are wasted annually in placing a greater thickness of material in places where it is not needed than in other places where a greater thickness is essential."

Must Show Earning Capacity

In speaking of the big program planned, Thomas H. MacDonald, chief of the United States Bureau of Public Roads, said, "Just now we have literally a pocketful of money. Funds have been made available in large amounts by the Federal Government, the States, the counties and even smaller districts which have accumulated because of non-expenditure. The earning capacity of our roads must be demonstrated, however, for we should not be hypnotized into the belief that this condition will continue to exist."

The fundamental engineering problem, MacDonald stated, was the inter-relation of the motor truck and the road.

"There is no doubt," he said, "that the design of motor trucks has been treated largely from the mechanical consideration of the construction of the vehicle itself. The development of these vehicles has taken place so rapidly that the adaptation of the vehicle to the roadways over which it is to be operated has been seriously neglected. On the other hand, the highway engineer is forced to give some consideration in his design of modern highways to the vehicles which are to be operated over them, and it is now time that the inter-relationship of the design of highways and the design of motor vehicles be recognized as a fundamental engineering problem without which the development of neither can go forward in a manner that will bring to the public the greatest service."

The Good Roads Show, which occupied the major part of the Coliseum, was given over to the display of road-building machinery, with a large number of trucks placed on view.

H. S. Berlin Elected President of Victor

SPRINGFIELD, OHIO, Feb. 15—H. S. Berlin, of Akron, has been elected president and general manager of the Victor Rubber Co. by the board of directors. The other executive officers chosen were: Vice-president, W. L. Timmons of Cleveland; secretary and treasurer, H. S. Burr, of Springfield; factory manager, Frank R. Talbott, of Springfield; sales manager, C. A. Swinehart, of Springfield. The new president and general manager has been in charge of one of the plants of the Firestone Tire & Rubber Co. of Akron, and has had extensive experience in the rubber industry. He succeeds H. H. Burr in the reorganization.

Announcement is made that orders for tires are being received by the Victor Co. in increasing volume. The factory is now running about 60 per cent on tires.

EDMUNDS & JONES SHOWS GAINS

DETROIT, Feb. 14—Profits of $108,226.01 for the year ending Dec. 31 are shown in the annual report of the Edmunds & Jones Corp. Assets aggregating $2,347,382.27 compare with $2,395,080.91 at the close of 1919. Current assets of $1,319,714.47 and current liabilities $532,746.98 compare with $1,468,791.64 of current assets and $479,733.00 current liabilities the previous year. Working capital in 1920 was $786,967.49 compared with $989,058.64 in 1919. Plant investment is given at $990,940.03, an increase from $900,558.79.

Surplus representing the book value of 40,000 shares of no par common stock after allowances for Federal taxes and deductions of dividends of 7 per cent on preferred and $2 on common was $959,409.15, compared with $1,016,997.83 at the end of 1919. Outstanding preferred was reduced from $890,400 to $843.200 by purchase and redemption, making $156,800 retired by that method.

Highway Educators Meet at Ann Arbor

Many National Figures to Address Conference—Ex-Secretary Redfield on Program

ANN ARBOR, MICH., Feb. 11—Under the auspices of the permanent committee on Highway and Highway Transport Education, the University of Michigan and the Michigan State Highway Department, a mid-western conference on highway and highway transport education will be held here Feb. 23. The program will be as follows:—

Morning session, 10:00 A. M., Auditorium, University Hall; Dr. P. P. Claxton, U. S. Commissioner of Education, presiding; "The Highway and Social and Economic Welfare," by Dr. Claxton, chairman of the permanent committee; "The Educational Activities of the Permanent Committee," by Professor C. J. Tilden, director of the permanent committee; "The Economics of Highway Transport," by Roy D. Chapin, vice-president, National Automobile Chamber of Commerce; "Highway and Highway Transport Education in Secondary Schools," by George C. Diehl, chairman, good roads board, American Automobile Association; "Safety First Education in Secondary Schools," by Harriet E. Beard, Supervisor of Safety Education, Detroit public schools.

Afternoon session, 2:00 P. M., Auditorium, University Hall, Dr. P. P. Claxton presiding: "The Measure of Highway Accomplishment," by Thomas H. MacDonald, Chief, United States Bureau of Public Roads; "The Army's Highway Transport Problem," by Col. Mason M. Patrick, Corps of Engineers, U. S. Army; "The Interrelationship of Waterway, Railway and Highway Transport," by Professor Henry E. Riggs, Professor of Civil Engineering, University of Michigan; "Snow Removal from Transport Routes," by Charles J. Bennett, State Highway Commissioner of Connecticut; "The Economic Value of Highway Transport Surveys," by Professor Arthur H. Blanchard, Professor of Highway Engineering and Highway Transport, University of Michigan.

Dinner will be served in the banquet hall of the Michigan Union at 6:00 P. M., Dr. Mortimer E. Cooley, president of the Society for the Promotion of Engineering Education, presiding. After dinner addresses will be "Highway Transport and the Industry," by Tom Snyder, secretary, Indiana Highway Transport & Terminal Association; "Interrelationship of Highway Transport and the Back-to-the-Farm Movement," by A. R. Kroh, Development Department, Goodyear Tire & Rubber Co.

At the evening session, with Dr. Marion L. Burton, president of the University of Michigan, presiding. "The Trinity of Transportation," will be, discussed by William C. Redfield, former Secretary of Commerce of the United States.

GASOLINE QUALITY HIGH

WASHINGTON, Feb. 11—Improvement in the quality of motor gasoline has been reported by the Bureau of Mines after a study of samples taken from representative garages throughout the country.

Seiberling Urges Stockholder Support

Merchandise Creditors to Take Shares If Not Sold—Stock Values Improved

(*Continued from page* 425)

to head a syndicate to underwrite the $25,000,000 20-year 8 per cent sinking fund bonds, proceeds of which will go toward paying off the bank debt. While no decision has been reached in the matter, it is not unlikely that the balance of the financing, consisting of $25,000,000 10-year 8 per cent sinking fund debentures, 250,000 shares of common stock and $35,000,000 8 per cent prior preference stock will be underwritten by another banking group. The $25,000,000 debentures, 250,000 shares of common stock and $35,000,000 prior preference stock is to be offered for subscription to existing common and preferred shareholders of the company at prices to be determined by the committees in charge of the plan, and these securities or the proceeds from their sale will be used to satisfy other claims and for other corporate purposes.

Under the plan, if none of the prior preference stock is sold, practically the entire $35,000,000 will be divided among the merchandise creditors, who are split into two groups.

One group represents creditors to whom the company's indebtedness existed on Jan. 1, 1921, and whose claims aggregate $15,395,660. They will receive 125 per cent of their claims in prior preference stock, or $19,244,575 par value.

The other group represents creditors with whom the company has made commitments for merchandise not delivered prior to Jan. 1, 1921, but for which specifications and prices have been fixed. Their claims aggregate $54,959,503, for which they will receive 75 per cent in cash, payable not later than the tenth of the month following shipment from American point of shipment, and 28 per cent in prior preference stock, which amounts to $15,388,660 par value.

Will Write Down Inventory

The company contemplates "writing down" its inventories and commitments, and converting part of the difference between the cost and market value of raw materials into prior preference stock, so that the company's earning ability may be immediately enhanced and also so as to bring nearer dividend payments.

The refinancing wipes out the company's deficit, and will enable it to operate on costs based on present market value and to resume earnings.

"While the present low market prices of our stocks do not look good to those who hold them, we feel that the value of these stocks is made more secure and the future prospects are made brighter by the plan which proposes to relieve us of the dangers of pressure by our creditors," says a Goodyear statement.

EMPLOYEES AGREE TO WAIT FOR WAGES

DETROIT, Feb. 14—Penberthy Injector Co., which has been working on a two-day week schedule, began work to-day on a five-day schedule under a deferred wage payment plan submitted by officials and accepted by employees.

Under the plan employees will be paid cash for three days each week and the balance credited to their accounts. Cash on the deferred wages will be paid on a sliding scale proportionate to the volume of business as it increases.

The plan was proposed to give opportunity to all employees to make sufficient money to maintain themselves, and to give the company an opportunity to work up its stock in materials, which is estimated to last six months. Officials of the company are confident of early improvement in business and look forward to paying the deferred wages within a few months.

Willys-Knight Output of 2 Daily Scheduled

TOLEDO, Feb. 14—The Willys-Overland Co. posted its first production schedule this year to begin to-day of two Willys-Knight sedans daily.

This schedule will keep the small force of men, about 1600 now employed at the plant, busy. Parts of the cars are already built. Men have been busy rectifying some cars in the factory for several weeks.

That the market at the present time in the whole country is just at the balance point where talk of further price reduction, new models, or other disturbing elements might set the industry back several weeks is the thought of Mr. Wilson, in charge of Overland operations.

He feels that the industry has made a move in the right direction during the last two weeks and that conditions appear to be coming right.

Industry has picked up about as much as bank clearings, three per cent. That's the general opinion of the Overland officials.

CHARLES R. STEPHENS DIES

MOLINE, ILL., Feb. 14—Charles R. Stephens, son of George W. Stephens, founder of the Moline Plow Co., and for 27 years intimately associated with the business, died suddenly Wednesday at his home in Los Angeles. Mr. Stephens had not been interested in the company since it was acquired in 1918 by the Willys interests.

He was superintendent of the plant for 18 years, a director of the company nearly as long and in later years director of the foreign sales department. He made a notable record as shop superintendent. Mr. Stephens was born in Moline, June 8, 1862.

Bosch Wage Scale Cut 12½ Per Cent

Company Takes Conservative Position on Dividends—Extension of Markets Helpful

SPRINGFIELD, MASS., Feb. 15—The American Bosch Magneto Corp. has announced a wage reduction of 12½ per cent affecting all factory employees whether on a weekly or piece work basis. Operations in the plant are being steadily increased and several hundred men are now employed.

The directors of the company will meet late this week for action on dividends and it is reported payments will be reduced. Although the company has about $6,000,000 of orders on hand it is said the directors are inclined to take a conservative position on the dividends pending improvement of business conditions.

Arthur T. Murray, president of the company, has sent out a review of the corporation's business since its inception. This shows that in 1916 sales were slightly more than $4,000,000 and that in 1918 under the old company and the alien property custodian they had fallen to $3,656,000. The sales of the new American company in 1919 were $5,982,000 and in 1920 they had increased to $8,805,000.

Murray devotes considerable attention to the taking over of the management of the Gray & Davis plant at Cambridge and its lamp factory at Amesbury under terms most favorable to the American Bosch Magneto. The product of the Bosch company is now very diversified. The magneto department is depending on the automobile trade for not more than 20 per cent of its business.

The growing demand is in the field of farm engines, tractors, trucks, marine engines and other trades in which the internal combustion engine plays an important part. The company also is equipped to enter the automotive field with battery ignition systems, starting and lighting systems, spark plugs, etc.

R. & V. MAKES WAGE REDUCTION

EAST MOLINE, ILL., Feb. 14—Wage reductions approximating 15 per cent have been adopted by the R. & V. Motor Co., affecting men in all departments and those upon a piece work basis. Employees laid off and returned to work during the period of the depression accepted the lower scale upon their return. H. A. Holder, president of the company, announcing the reduction, told employees that there is absolute necessity for readjustment of costs.

BUFFALO S. A. E. TO MEET

DETROIT, Feb. 11—The Buffalo Section of the Society of Automotive Engineers will meet at the University Club, Buffalo, Feb. 23, at 8 p. m. Ferdinand Jehle, of the Aluminum Mfg. Corp., Cleveland, will present the paper.

Industry as Whole Must Unite on Tax

Destructive Effects of Proposed Action Must Be Shown at Congressional Hearings

(*Continued from page* 424)

can easily pay the tax and the man who has no business to run a car because of his circumstances must let go." The pernicious effect of this assumption is readily apparent when it is remembered that these views are handed out to other legislators.

The problems of the present session have been too perplexing to allow Senators and Congressmen to give adequate study to the ultimate effects of the Houston program. It will be the duty of representatives of the industry to enlighten them at hearings which probably will be held early in April. Officials of the Treasury Department already have appeared before the Senate and House committees. Senator Curtis and other leaders have stated that the books must be balanced before July, indicating that discussion of internal revenue matters will be limited and the most appealing plans will be accepted.

The Secretary of the Treasury in suggesting sources of additional revenue advised Congress that "the suggested list of consumption taxes have not been selected because their use is particularly harmful OR IN ANY SENSE LESS LEGITIMATE THAN THE USE OF ARTICLES NOT SO INCLUDED."

The Secretary has declared that consumption taxes must be considered from practical standards. Sentiment has developed in favor of the Treasury program chiefly because it affords the easiest way out of a tremendous problem. Imposing heavy taxes on a selected list would eliminate legislation for petty taxes and Congress does not intend to hunt for work. There has been considerable agitation for a sales tax, however, and the movement seems to have gained headway.

Information has reached numerous Congressmen that the automotive industry is disposed to treat the Treasury plan lightly. Legislators have stated that the most serious thought will be given the Secretary's plans because he is in a position to know the nation's needs. It also has been asserted that the proposed tax of 2 cents per gallon on gasoline at refineries would be defeated because of the influences of the oil interests but there is nothing to support this encouraging assumption.

Organizations Will Confer on Program

(*Continued from page* 424)

heavily with Congress because of the political dynamite it contains.

C. C. Hanch, chairman of the N. A. C. C. tax committee and former general manager of the Maxwell Motor Co., who has been devoting much of his time to the formulation of the tax program, expects to spend several days consulting with representatives of other automotive organizations concerning their tax ideas. Hanch and his committee have not determined whether protest against additional taxes on automobiles would carry greater weight at Washington if they were presented by the industry as a whole or by each organization separately on a different hearing date. No decision has been reached as to who will make the argument for the N. A. C. C. before the ways and means committee. Some members of the tax committee feel it should be presented by an expert on economics rather than by a lawyer.

M. A. M. A. to Discuss Action

Directors of the Motor & Accessory Manufacturers Association will consider the tax question at a meeting here Friday and it is probable a special committee will be appointed to take up the question. Sentiment in this organization is in favor of some sort of sales tax. M. L. Heminway, general manager, feels that concerted action should be taken by the industry against such a menace as heavier Federal taxes. He is willing to go to any reasonable length to bring about such action.

The tax committee of the Rubber Association of America also is committed to a sales tax but on a somewhat different basis from that proposed by the N. A. C. C. A. L. Viles, the general manager, is firmly convinced that arguments in Washington will carry much greater weight if they come from the industry as a whole rather than from different branches of it.

The National Automobile Dealers Association adopted a resolution at its recent convention in Chicago declaring that it was in complete accord with the program of the N. A. C. C. calling for the reduction of war-time expenditures by the Federal government and a return of the government to normal. Harry G. Moock, the general manager, says the two associations will work in complete harmony on the question of tax policy. He has under contemplation a plan whereby the dealers will appoint a tax committee to meet the tax committee of the N. A. C. C. and learn how the two organizations can work together.

The American Automobile Association is expected to stand with the N. A. C. C. on the tax question.

N. A. C. C. Firm for Plan

It is probable a conference of representatives of various organizations will be held in the near future to discuss the possibility of united action. It is not known whether the N. A. C. C. would be willing to modify its program if it does not meet with the entire approval of the other organizations. It has been suggested that the Motor Vehicle Conference Committee or a similar organization representing all branches of the industry might be used in future to map out action on questions which involve the industry as a whole.

Post Office to Probe Junker Plane Loss

Accident in Which Three Lives Were Lost to Be Given Thorough Investigation

WASHINGTON, Feb. 11—Officials of the Air Mail Service announced today that a thorough investigation would be conducted into the explosion of the Junker plane at LaCrosse, Wis., yesterday, which resulted in a loss of three lives. Chief of Flying Operations Collier stated that the mechanical faults which had been responsible for the destruction of other J L planes had been eliminated, so that it was difficult to determine the cause of the fatality.

The mechanicians employed by the Postal Service are unwilling to believe that it was the fault of the gas system. The wrecked plane had been completely overhauled and a new fuel feed system installed following accidents to other planes. The fuel system was known as "fool-proof." It was devised to allow leaking gas to fall to earth rather than in the fuselage and invite explosions.

The machine, J L 301, had been in service four months. The authorities have two theories to advance. Either the pilot lost control of the elevators or some difficulty caused loss of flying speed and the machine crashed to earth as a result. Reports establish the fact that there were no signs of fire before the machine was smashed.

Because of the defense of purchases of these planes made by the Postmaster-General and endorsement of their superiority over American planes, it is expected that the latest accident will incite an attack against encouraging foreign aircraft makers as against the new industry in this country.

Larsen Defends Plane

NEW YORK, Feb. 15—J. L. Larsen, sales agent in this country for Junker planes, has sent out a statement in which he asserts that the mail airplane which crashed at La Crosse did not catch fire in the air. He asserts that the machine circled twice across the landing field, losing altitude preparatory to landing, with the motor hitting perfectly, but when at an altitude of 500 ft. it nosed down for some unknown reason and crashed, taking fire after it struck.

Larsen complains that undue prominence has been given to this accident in contrast to the small space given an accident to a De Haviland on the same route a week previously when the pilot was killed and the mechanic seriously injured. He asserts that the German plane was making its first trip over the Chicago-Minneapolis mail route with men new on that line. Larsen adds that mechanical changes made by the air mail service were not in accordance with the German practice, so he is not in a position to state whether the machine was safe for flying.

Business and Sport Share S. A. E. Program

West Baden Springs Hotel Offers Unusual Facilities for Meet —To Push Researches

NEW YORK, Feb. 15—Following the custom of previous years, the Society of Automotive Engineers, at its annual summer meeting, will hold but one engineering session each day, the remainder of the time being given to sports and recreation with a series of house lectures and dancing in the evenings. The engineering sessions will be from 10 to 1 o'clock. The meeting this year is to be at West Baden Springs, Indiana.

The West Baden Springs Hotel with accommodations for 930 guests is well suited for the special meeting because of its isolation among the hills of southern Indiana. It provides every facility for golf, horse back riding, tennis, bathing and field sports as well as for summer meetings. The hotel is circular in shape, six stories high and has a glass covered central court which is the largest room of its kind in the country.

West Baden is famed for its mineral waters and mineral and mud baths, all of which are a part of the hotel system. The hotel has a large swimming pool and a complete bath equipment. Within five minutes walk of the hotel is a sporty 9 hole golf course. There are two other golf courses within five miles of the hotel.

West Baden is on the Monon Railroad, 126 miles southwest of Indianapolis and 60 miles north of Louisville. Good roads radiate in nearly all directions.

The meetings committee for 1920 under the chairman, C. F. Scott, has already drafted a comprehensive program based on one session of three hours for each subject. The opening day, May 24, will be given over entirely to standardization and meetings of the standards committee. Other subjects to be considered are aviation, farm tractors and fuel research. Research work this year will play a more important part than ever before in the activities of the S. A. E. in view of the appropriation of $30,000 which has been made to foster it.

Committee to Engage Man

During the past year the S. A. E. has worked on fuel research and this will be continued but there are many other research activities which may be carried on, among them radiator temperatures and gear tooth pressures. Additional subjects are being considered by the research committee headed by H. M. Crane.

A special research man will be engaged to handle the work under the direction of the research committee. He will be an expert familiar with all branches of research. Some effort will be made to obtain the co-operation of companies engaged in various lines of research. It has been estimated that there are as many as a dozen of these companies. It is not the intention of the S. A. E. to open a laboratory but its work will be carried on in laboratories of companies in the automotive field. Co-operation of government bureaus such as the Bureau of Standards and Bureau of Mines will be obtained as well as that of Universities and engineering schools.

Crane and his committee have not drafted any comprehensive line of research but the program will grow gradually and committees will be organized as it progresses along lines similar to the expansion of the standards committee during the past nine or ten years. Members of the committee besides Crane are E. A. Johnston, C. F. Kettering, H. L. Horning, J. G. Vincent, H. W. Alder, Dr. H. C. Dickinson, T. C. Menges, Joseph Van Blerck, and O. C. Berry.

Midwest Tire Makers Hear Cooperation Plea

CHICAGO, Feb. 15—The Midwest Rubber Manufacturers Association held its regular monthly luncheon and meeting at the Chicago Athletic Club to-day. The principal speaker was Thomas Whitehead, president of the National Tire Dealers Association, a new association formed during the Chicago automobile show for the purpose of bringing into one national organization the best tire dealers of the country.

Whitehead's remarks inspired those present with the feeling that before long every community of any size will have its local chapter, the purpose of which will be to eliminate the "gyp" method of selling tires so prevalent in the past. Whitehead assured the tire manufacturers present that an ever-ready spirit of co-operation would be found by the members of the association to bring the merchandising of tires to a higher plane than ever before but demanded that a like spirit prevail among the manufacturers to do their part in the work.

AUTO BODY SHOWS GAINS

DETROIT, Feb. 14—Assets of $2,674,-906.02 and surplus of $48,035.28 are given in the balance sheet of the Auto Body Co., as of Dec. 31. Current assets were $1,515.006.50 and current liabilities $1,070,490.69 compared with current assets of $1,211,709.04 and current liabilities $714,934.39 in 1919. Working capital at the end of 1920 was $444,515.81 against $496,934.63 a year ago. Fixed assets were $1,095,329.57 against $1,090,743.06 in 1919. Outstanding preferred stock amounted to $531,500, an increase from $527,600 during the year, and outstanding common was $1,018,500, an increase from $1,017,400. Total assets for the previous year were $2,339,216.29 and surplus, $49,782.

DANIEL SOUTHERN RECEIVER

GREENSBORO, N. C., Feb. 14—Garland Daniel of Greensboro has been named as receiver for the affairs of the Southern Truck & Car Corp., large manufacturers of commercial motor trucks, the action being taken as a protection to the stockholders of the company. The corporation is capitalized at $1,000,000.

METAL MARKETS

ALMOST every new transaction in the iron and steel market, if at all representative in point of tonnage involved, records lower price levels. This successive shading of prices, however, does not denote a fresh downward readjustment of the market. It is but the consummation in actual sales of what has been a theme for abstract discussion since last November. To be still more precise, it is the beginning of this consummation. As to its culmination, there is no telling. The manner in which prices are beginning to tell the market's readjustment, is, however, no less gratifying to the seller than to the buyer. For weeks and weeks iron and steel producers found it utterly impossible to secure orders at any price. They knew this and continued to quote unchanged prices because concessions would have proved useless bait. In the last few days it has become evident that there is some business to be had, not spectacular in tonnage but actual, honest-to-goodness orders. To "land" this business, it was necessary to quote prices in keeping with the changed order of things. It was the first reawakening of genuine consuming demand and steel producers were too pleased at sight of this blossom, tender as it still is, to lose very much sleep about how sharp price cuts would have to be in order to get this business on their books. In fact, for some time the instructions of all "independents" to their sales executives have been to corral all business in sight, at whatever price it was necessary to quote. The only reason that the "independents" did not cut under the Corporation's levels before, was that there was no business to be had at any price. Press reports from the Youngstown district of sharp price reductions by one of the leading independents, were largely for the benefit of labor agitators who, otherwise, might have taken reductions in wage scales with less grace. To sum up the situation, the Corporation's prices have now become obsolete, in so far as new business is concerned. Quotations of independents are sufficiently elastic to include serious consideration of any and all bids that consumers might be tempted to make, so long as specifications are attractive.

Pig Iron.—With basic pig iron offered at as low as $25, furnace, the price of foundry and malleable suitable for automotive foundries, is problematical. Sales of the latter have been made in small tonnages at around $29, valley. Practically all of the automotive buying is in carload lots.

Steel.—Most of the buying by automotive interests consists of filling in or matching up tonnages. Fair-sized tonnages of sheets, however, are reported to be going forward from Pittsburgh district mills to Detroit passenger car builders, especially to those manufacturing medium priced passenger cars. The Reo Motor Car Co. and Buick Motor Co. are among those who have been ordering sheet shipments forwarded.

Aluminum.—Placing of orders with automotive foundries for aluminum castings is reflected in a somewhat better demand for No. 12 alloy. The "outside" market for virgin ingots, 98 to 99 per cent pure, has receded to around 24½ cents.

Lead.—The American Smelting & Refining Co. reduced its official quotation $3 a ton to a basis of 4.60c., New York and East St. Louis. In the "outside" market the New York quotation is on a parity with that of the chief interest and East St. Louis is quoted at 4.30c.

FINANCIAL NOTES

D'Arcy Spring Co. plans to increase the capital stock from $75,000 to $1,000,000. Of this amount $650,000 will be common stock and the balance of $350,000 will be 8 per cent preferred stock. Application has been made to the Michigan Securities Commission allowing the proposed increase. Up to this time the D'Arcy Spring Co. has been a closed corporation, but the new stock will be offered to the public, and it is planned to give the new shareholders representation on the board of directors. Preferred stock to the value of $150,000 will be offered first.

Knickerbocker Motors, Inc., Poughkeepsie, N. Y., has filed schedules in bankruptcy with liabilities of $200,771 and assets of $89,678 and other assets of value unknown. Machinery, etc., is valued at $16,047; accounts $72,736. and deposits in banks, $894. Among the creditors are the estate of Herbert G. Streat, $72,569; First National Bank of Poughkeepsie, $15,919, and Irving National Bank, $20,770.

Stewart Warner Speedometer Corp. reports net income for 1920 of $2,728,472, as compared with $2,331,915 for the previous year. The amount available for the capital stock, $2,210,000, was smaller than in 1919 owing to increased taxes and a large amount of stock outstanding. This was equal to $4.83 a share on the 457,525 shares, as against $4.90 on the 400,000 shares outstanding at the end of 1919.

Pierce-Arrow Motor Car Co. stockholders, both common and preferred, numbered 4730 on Jan. 1, an increase of 1210, or about 35 per cent above the total of Jan., 1920. The number of holders of common were 2880 and preferred 1850, compared with 1800 and 1720 the year before.

Supreme Motors Corp. is offering through W. A. Fennell & Co., Cleveland, $1,500,000 first mortgage 8 per cent convertible bonds due annually Jan. 1, 1923 to 1929, inclusive. The proceeds will be used to retire current indebtedness and increase working capital.

Federal Motor Truck Co. reports profits before Federal taxes of approximately $745,878.66 for 1920. Taxes are estimated at $200,000. Total sales were $10,628,742.09 Total assets are $4,525,340, and the surplus for the year $806,812.

Hill Insulating & Mfg. Corp., New York, has filed a petition in bankruptcy with liabilities of $24,161 and assets of $6,079, the main items of which are stock, $2,500; machinery, etc., $2,000, and accounts, $1,494.

Rey Wheel Co. has increased its board of directors from five to eight, adding James C. Kempton, of the Detroit Sales Co.; William Roberts, of Roberts Tube Works, and C. R. Aikman, of Amherstburg, Ont.

Packard Motor Car Co. declared the regular quarterly dividend of 1¾ per cent on the preferred stock payable March 15.

Parker Creditors Vote Confidence in Officers

MILWAUKEE, Feb. 11—Absolute confidence in the present officers and directors of the Parker Motor Truck Co. is voiced by the creditors' committee appointed on Dec. 13 which has been investigating the conditions of the corporation. It is felt that with the consent of the creditors the affairs of the company can be carried on without recourse being taken in the appointment of a receiver.

The company is a reorganization of the Stegeman Truck Co. which two years ago found itself in financial difficulties. The new company took over and assumed all accounts of the Stegeman company and has paid about 75 per cent of them.

A large amount of money was found necessary in entirely rebuilding and redesigning the Stegeman product to bring it up to its present efficiency.

Emerson-Brantingham Shows Drop in Earnings

ROCKFORD, ILL., Feb. 11—With the plants of the Emerson-Brantingham Co. operating at the present time at about 75 per cent of capacity, a moderately profitable business for this year is forecast in the annual statement of President C. S. Brantingham.

Earnings of the company during the past year were materially reduced but the company transferred $20,768 to profit and loss surplus after payment of the 7 per cent preferred stock dividend. In the previous year there was a surplus of $470,484. The income account for the fiscal year ended Oct. 31, 1920, together with the balance sheet at the end of that period, compares as follows:

INCOME ACCOUNT

	1920	1919
Op. profit, after tax	$1,512,857	$1,837,225
Other income	412,695	409,785
Total income	1,925,552	2,347,010
General expenses	*419,329	403,311
Net income	1,506,226	1,843,699
Interest	453,087	339,444
Depreciation	180,435	181,835

Total	$35,678,352	$29,865,031

PEERLESS REDUCES DIVIDEND

CLEVELAND, Feb. 14—The cut in the dividend rate of the Peerless Motor Car Co. is ascribed by directors to the desire of the company to protect its future interests. The cut is the second that has been made and reduces the rate to 4 per cent on the par value of $50.

Bank Credits

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, Feb. 17—The local money market eased the latter part of last week. Call money ruled at 8 per cent the first two days of the week and at 7 per cent thereafter. The range for the week was 7 per cent to 8 per cent as against 7 per cent to 9 per cent the week before. Time money was firm with a light supply. Sixty and ninety days' and four months' paper was quoted at 7 per cent, and five and six months' paper at 6¾ per cent, the same as the week previous. One of the principal causes of this firmness was, apparently, the large withdrawals by the South and the West, as indicated by the week-end bank statements.

The statement of the New York Associated Banks showed further contraction and may explain to some extent the easier call money towards the close of last week. The excess reserves over legal requirements increased $4,250,480, and loans declined $72,943,000. This is the largest reduction in loans since the second week of January.

The New York Federal Reserve Bank, in contrast with the previous week's operations, showed an improved reserve position. Gold reserves increased $10,328,000, and total cash reserves $15,167,000. Total bills on hand declined $25,198,000, and total earning assets $22,896,000. Federal Reserve notes in circulation in this district declined $8,554,000, while Federal Reserve bank notes increased $4,314,000.

G. M. C. Sales Increase; Net Profits Decrease

NEW YORK, Feb. 17—A preliminary report of the General Motors Corp. for the year 1920, issued to-day, shows a gross business of $565,000,000, an increase of $56,000,000 over the preceding year and the largest in the history of the company but the net profits of $48,262,000 available for dividends, were $11,800,000 less than in 1919. Total current assets were $263,939,000 and current liabilities $115,554,000. This left a net working capital of $148,395,000. Cash in banks on Dec. 31 totalled $49,278,000 and sight drafts, notes and accounts receivable to $48,661,000. Notes payable amounted to $72,225,000 and accounts payable and trade acceptances to $25,794,000.

The finance committee of General Motors Corp. is considering the advisability of wiping out bank loans of approximately $75,000.000 through the sale of new securities. General Motors has no immediate need for funds for any purpose other than the elimination of its loans and it is simply a question of policy whether the banks should be paid off at this time.

The company is considering sales of some of its factories and W. C. Durant is reported as having made offers.

MEN OF THE INDUSTRY

Homer Hilton, sales manager of the Oshkosh F. W. D. truck, who is leaving that organization, has been sent to Detroit to take charge of the office of the National Association of Truck Sales Managers, pending the selection of a successor to H. D. Dabney, secretary. Dabney joined the organization last June, and his resignation will become effective March 15. He said he was not ready to announce future connection. A committee from the association now is in communication with several applicants for the position, and announcement of an appointment is expected shortly. Hilton, who is one of the best known members of the association, will spend a month or two in the local office inducting the new secretary before assuming other duties which he now has in mind.

W. J. Corr has been elected secretary and treasurer of the Maibohm Motors Co., Sandusky, Ohio, succeeding I. O. Bormann, resigned. Corr has been director of purchases for the Maibohm company for the past year and is widely known in the automotive industry. He was with the General Motors for the first two years following its organization, doing purchasing, cost and systematizing work at the Northway, Cadillac and Oakland plants. For the following two years he was director of purchases of the Apperson Brothers Automobile Co., then for two years director of purchases of the Falls Motors Corp. For nearly three years prior to joining the Maibohm organization he was purchasing agent for the Detroit plant of the Aluminum Castings Co.

Fred R. Wilhelmy, for many years with the Standard Parts Co. of Cleveland and its predecessor, the Standard Welding Co., in the financial and credit end of the business, has announced his resignation from that company, effective Feb. 15. Wilhelmy has always been active in get-together affairs of the trade, particularly where credit men were concerned, and is well known throughout the industry. His future plans have not been divulged.

K. T. Keller has been appointed manager of manufacturing of the Chevrolet Motor Co., succeeding F. W. Hohensee, who resigned to join the new Durant Motors organization. Keller has been in the General Motors organization since 1911, having served as superintendent at the Northway Motor & Mfg. Co., general master mechanic at the Buick Motor Co. and as a member of the general operations staff at the corporation offices in Detroit.

L. Grant Hamilton has just joined the staff of the Akron Advertising Agency, Akron. Hamilton, since the war, has been in active charge of the advertising of the Federal Motor Truck Co. Prior to the war, Hamilton was with the Campbell-Ewald Agency. He also served as advertising manager of the Regal Motor Car Co. and was a member of the advertising and sales promotion departments of Studebaker.

T. B. Blakiston has succeeded J. H. Quackenbush as general sales manager of the American Hammered Piston Ring Co., of Baltimore. Blakiston was formerly sales manager for the southeast district. S. A. Barclay was appointed to succeed Blakiston in this territory. A. N. Merrifield has been placed in charge of the western and Chicago sales districts, replacing D. T. Preyer.

B. F. McDonald, former works manager and lately general superintendent of the Moline Plow Co., has joined the Rock Island Plow Co., as factory manager. T. B. Fuller has succeeded him as works manager in the Moline Plow and A. C. Blair has been named general superintendent of that organization.

Roy M. Hood, purchasing agent for the Maxwell Motor Co., has left that organization and has been succeeded by A. C. Downey, formerly of the Willys-Overland staff at Toledo. Hood said he had several plans under consideration, but would not be ready to announce them for several days.

A. J. Riggs, of Racine, Wis., has been appointed general sales manager of the E. L. M. Tire & Rubber Co., of Racine, a new $200,000 corporation organized a few months ago to manufacture tires, tubes, mechanical rubber goods, etc., using as a plant nucleus the E-Z Rubber Heel Co. factory in that city.

M. F. Emrich, formerly vice-president and general manager of the Campbell Paint & Varnish Co. of St. Louis, a subsidiary of the Glidden Co., has recently been appointed general sales manager of the industrial division of the Glidden Co., with headquarters at Cleveland.

R. M. Guyer, formerly with the Dort Motor Co., has been made general manager of the Miller Auto Top & Body Co., of Caro, Mich. The following officers have been elected: President, George Van Tine; vice-president, P. A. Miller; secretary-treasurer, M. G. Atwood.

Guy C. Core, who has been advertising manager for the Jackson Motors Corp. for about a year, has resigned from that organization. Core has announced no future connection, and no appointment has been made to the vacancy in the Jackson office.

Earl L. Woods has been elected a director and vice-president of the Horse-Shoe Rubber Co., St. Louis and Kansas City, and will assume charge of the Kansas City territory. Woods was formerly sales manager for the J. I. Case Plow Co.

Edmund Otto, formerly secretary of the Hardware & Supply Co., has joined N. B. Payne & Co., New York, and will be connected with the department handling portable conveyors, coal elevators and other machinery.

D. H. Roberts, sales manager of the Latex Tire & Rubber Co., Fond du Lac, Wis., has been promoted to the post of general manager, in charge of operation, production, as well as sales and advertising.

Bob Crowthers has resigned his position with the Gary Motor Truck Co. and has joined Master Trucks, Inc., Chicago, in the capacity of advertising manager and assistant sales manager.

C. M. Eason, vice-president in charge of sales for the Hyatt Roller Bearing Co. resigned, effective Feb. 1. Ben G. Koether has succeeded Eason in charge of sales at the Hyatt factory.

R. C. Huddle has been appointed purchasing agent of the O. Armleder Co., Cincinnati, succeeding W. R. Hill, resigned.

W. J. O'NEIL DIES

AKRON, Feb. 14—William J. O'Neil, founder and president of the O'Neil Rubber Co., of Akron died suddenly of apoplexy, Thursday, while en route to his office. Mr. O'Neil was riding in the machine of A. H. Palmer and suddenly slumped forward, life being extinct before Mr. Palmer could summon aid.

Mr. O'Neil resigned from the B. F. Goodrich Co., eleven years ago to establish the company.

INDUSTRIAL NOTES

Palmer Tire Corp., Poughkeepsie, N. Y., has discontinued rebuilding tires and will build an addition to the factory for the manufacture of 30 x 3½ tires and tubes exclusively. The new product will be known as the Henry tire and tube. C. J. Davis, Akron, has been engaged to assume charge of manufacturing. A New York office will be opened at 5 Columbus Circle.

Caddenhead Auto Rim Co. has begun construction of its $100,000 plant at Tarrant City, Ala., where automobile rims and steel products will be manufactured, the daily capacity of the plant to be 3000 rims. Initial production will be about 400 or 500 rims daily. The company is headed by J. T. Caddenhead, prominent in business circles in the Birmingham district.

Atlas Metal Stamping Co., Inc., has taken over the business of Isidor Blickman. Noah Wollman Amdur will be president under the new organization of the company, and Mr. Blickman, treasurer. The headquarters of the company have been moved from New York to Brooklyn.

Highway Motors Co., Defiance, Ohio, will soon start the erection of a plant for the manufacture of tractors and truck motors. Charles H. Kettering of Dayton is president of the company, which has been making passenger cars exclusively.

Acme Wire Co., New Haven, Conn., has opened a Chicago office in charge of H. B. Bassett. The company also maintains branch offices at Cleveland, in charge of J. T. Crippen, and in New York, in charge of H. S. Glasby.

American Tire Fabric Co. closed operations Saturday. How long it will continue the officials here are unable to say, but they believe it will be for two weeks at least. About 300 hands are employed at the mills.

Dodge Mfg. Co. has taken over the Burnoil Engine Co. of South Bend, Ind., and sales of this product will be handled by the Oil Engine Division of the Dodge Sales & Engineering Co., Mishawaka, Ind.

O. Armleder Co. has opened a branch to serve the New York district at Third Avenue and Butler Street, Brooklyn. John S. Hyatt will be manager and A. W. Christopher sales manager.

Hoosier Auto Parts Co. has changed its name to the Hoosier Clutch Co. The business of the company will be continued at Muncie, Ind.

Kroyer Motors Co., Stockton, Cal., has awarded contracts for a factory unit in which will be manufactured the Wizard 4-pull tractor.

CLIMAX RUBBER MOVES PLANT

COLUMBUS, Feb. 14—The annual stockholders' meeting of the Climax Rubber Co., held at the home office here approved plans as submitted by officials. The company recently sold its Huntington, W. Va., plant and secured the plant of the K. & W. Rubber Co., at Delaware, Ohio, to which the machinery and equipment from the Huntington plant were removed. The Delaware plant has now become the main plant. Irving S. Hoffman was elected president; Herman A. Longshore, vice-president; Clyde B. Turner, secretary and treasurer, and E. W. Pavey, sales manager.

Calendar

SHOWS

Feb. 19-26—San Francisco, Fifth Annual Pacific Automobile Show, Exposition Auditorium, George Mahlgreen, Mgr.

Feb. 21-26—Louisville, Annual Automobile Show, Louisville Automobile Dealers Ass'n, First Regiment Armory, C. L. Alderson, Secy'.

Feb. 21-26—Salt Lake City, Annual Automobile Show. Intermountain Automotive Trades Ass'n, W. D. Rishal, Mgr.

Feb. 26-Mar. 5—Buffalo, Annual Automobile Show, Buffalo Automobile Dealers Ass'n, 74th Regiment Armory, C. C. Proctor, Mgr.

Mar. 2-10—Des Moines, Annual Automobile Show, Coliseum, C. G. Van Vliet, Mgr.

Mar. 5-12—Atlanta, Annual Automobile Show, Atlanta Automobile Dealers' Ass'n, Auditorium, Virgil Shepard, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 5-12—Pittsburgh, Annual Automobile Show, Automotive Ass'n, Inc., Motor Square Garden, J. J. Bell, Mgr.

Mar. 5-12—Atlantic City, Annual Automobile Show, Automobile Trade Association of Atlantic City, Million Dollar Pier, A. H. Generatzky, Mgr.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 7-12—Nashville, Annual Automobile Show, Nashville Automobile Trade Ass'n, Page Bldg.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

Mar. 14-19—Washington, Annual Automobile Show, Washington Automobile Dealers' Ass'n, Rudolph Jose, Chmn.

Mar. 19-26—Detroit, Annual Automobile Show, Detroit Automobile Dealers' Ass'n, Morgan-Wright Building.

April 3-9—Denver, Annual Automobile Show, Auditorium.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April— Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections

April, 1921—Sofia, Bulgaria, Tractor Trials, under the Bulgarian Ministry of Agriculture.

May 28-June 8—International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

October—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

CONVENTIONS

May 4-7 — Cleveland, National Foreign Trade Council

Oct. 12-14, 1921—Chicago, Twenty-Eighth Annual Convention National Implement & Vehicle Ass'n.

Mexico City Exhibit to Start April 10

NEW YORK, Feb. 14—The automobile show which will be held in Mexico City will be opened on April 10 and continue for fifteen days. The show was originally scheduled to be held in March, and automotive manufacturers have been at some difficulty to ascertain the exact time of the exhibition. However, according to advices just received, the time has now been definitely set.

Three of the main salons of the new National Theater will be devoted to the showing, and the expectation was expressed that a majority of the 42 American cars represented in Mexico would be on display. The National Theater is described as a building which has cost $20,000,000 and which has been under construction for a number of years. It is now nearly completed and its use for the automobile show has been granted by the Government.

The show will be under the auspices of Señor Pascal Ortiz Rubio, Mexican Secretary of Communications. The show manager is Señor Gustavo Alana, Mexico City publisher and one of the officers of the Automobile Club.

Walker to Increase Engine Production

CLEVELAND, Feb. 14—Announcement was made at the annual meeting of stockholders of the Walker Motor Co. in this city yesterday that production is running from 10 to 15 engines a day now and that by March 1 it is expected production will have been doubled. Officials of the company are working on a program that calls for maximum production of 100 engines daily, and they expect to attain their goal later in the present year. At present the Grant Motor Co. is taking the bulk of the Walker factory output.

The stockholders yesterday elected as directors H. A. Tremaine, F. H. Blackburn, D. A. Shaw, Ben F. Hopkins, Robert L. Gale and George Salzman. Tremain and Blackburn, of the National Electric Lamp Co., are new directors. Officers will be elected in two weeks.

Purchasing Agents Meet to Devise Fuel Contract

PITTSBURGH, Feb. 18—Members of the fuel committee of the National Association of Purchasing Agents are meeting at the William Penn Hotel today to discuss a fair, equitable and inviolate form of contract governing the purchase and delivery of coal. The meeting was called by President W. L. Dodge. Ernest H. Hawkins of the E. I. duPont de Nemours Co. is chairman.

It is the purpose of the fuel committee to reach some form of contract which may be standardized, and at a later meeting the Advisory Council will meet with representative coal operators, distributers and purchasers to secure their advice and co-operation.

KELSEY ELECTS OFFICERS

NEWARK, N. J., Feb. 11—At the annual stockholders meeting of the Kelsey Motor Co. the following officers and directors were elected: Ernest B. Slade, president; C. W. Kelsey, vice-president; Thomas J. Stewart, treasurer; F. D. Dorman, secretary and assistant treasurer. Directors, E. J. Churchill, A. E. Jennings, John R. Thomas, Charles W. Hoyt, Charles Abbott, E. I. R. Cadmus, and L. S. Tyler.

ERNEST H. FULLER DIES

SYRACUSE, Feb. 14—Ernest H. Fuller, treasurer of the Automotive Service Association of Syracuse, died here after an illness lasting six weeks. John H. Sickeninger has been elected to fill the vacancy.

Belgium to Again Add to Import Tax on Cars

PARIS, Feb. 14—The Belgian Government proposes a further increase in the import duties on automobiles which were trebled last June. Importers representing large American interests are fighting the proposal, but Belgian manufacturers insist on protection.

The Peugeot Automobile Co. has no intention of using its own capital for the erection of a factory in the United States, but it is negotiating with an American group for the sale of a license to construct its cars. The Americans have not yet obtained the necessary capital and the plan is in abeyance.

Pennsylvania Rubber Re-elects Officers

JEANNETTE, PA., Feb. 14—At the annual meeting of the stockholders of the Pennsylvania Rubber Co. the following directors were elected for the ensuing year: Herbert DuPuy, Charles M. DuPuy, Seneca G. Lewis, George W. Daum, and A. H. Price.

The directors subsequently re-elected the following officers: Herbert DuPuy, chairman of the board; Charles M. DuPuy, president; Seneca G. Lewis, vice-president and general manager; George W. Daum, assistant general manager; A. H. Price, treasurer; James Q. Goudie, general sales director; George W. Shiveley, secretary; C. G. Morrill, assistant treasurer, and H. H. Salmon, purchasing agent.

PARTS MAKERS HEAR FRITZ

CHICAGO, Feb. 11—The Chicago Association of Automotive Equipment Manufacturers is making a drive for increased membership. At the present time there are 50 members enrolled. At the last meeting of the association an address was made by George Fritz.

THE AUTOMOBILE

VOL. XLIV NEW YORK—THURSDAY, FEBRUARY 24, 1921 No. 8

Chicago Favored for Next National Tractor Show

Aftermath of Columbus exhibit not favorable except as to local attendance. Capacity for producing farm products in greater quantity considered the best argument for the sale of tractors.

By David Beecroft

NEVER before at a national tractor exposition has the attention of tractor manufacturers been concentrated on one particular individual as at the National Tractor Show held at Columbus. That particular individual was a farmer. He was and still is the enigma of the tractor manufacturer as well as of the retail merchandiser of farm equipment.

The exposition assisted in crystallizing opinion as to the farmer and the very general conclusion is that he is still very much a creature of environment and climatic conditions. In winter when nature sleeps he enters into a period of business somnambulance, a condition of business coma, which continues until the spring sunshine, when he again becomes a part of the business world and changing his habits becomes a different kind of individual, thinking as business men think. Seeing the tasks of the season ahead, he realizes that nature in its seasonal cycles will not wait for him and so he gets onto the band wagon, ends his buyers' strike, and comes into the buying market.

This opinion of the farmer is shared largely by tractor manufacturers and subscribed to by farmers, some of whom for 40 years have been tillers of the soil, and know their fellow farmers as the business man knows his fellow business man.

The farmer, like the manufacturer, is just emerging from that great national drunk and joy ride of money-making and luxurious spending which has spread over the country since the armistice. On awakening the morning after he is a little bewildered and requires time to collect himself.

The farmer stopped buying last fall when wheat fell from $2.60 to $1.50 per bushel; when corn dropped from $1.57 to 40 cents; when wool tumbled from 75 to 20 cents per lb.; when milk sold to the condensing factories at $3.40 for 12.5 gal. went to $1.70 and all the condensing factories closed with the sides literally bulging out of the condensed milk storage warehouses; when cotton dropped from 30 cents to 7, and when livestock reached lower records.

This farmer is no more disgruntled than bankrupt. He is akin to the man who did not buy stock at the lower level of prices and sees himself having failed to make a good deal of money when the price rose. These farmers are poor in bookkeeping mathematics rather than in actual values. Too many of them are counting their losses based on a book value of wool at 75 cents per lb. rather than 25 cents. In calculating just how poor and psychologically bankrupt they are many are endeavoring to figure out what it has cost them to raise a bushel of corn on what they have cultivated on land worth $400 an acre 10 months ago and to-day worth little over $200 per acre. They are doing all of their calculating on the high level of prices to arrive at their losses.

These farmers are not bankrupt, far from it. They are in many cases short of ready cash—they did not sell wheat or corn when the market was at the top. They were badly advised in many instances by county agents who urged them to hold for $2.00 wheat. To-day not a few of these same county agents are advising them not to buy agricultural machinery until the price comes down; even worse in some agricultural states, rumors have been spread to the effect that certain branch houses and distributors of farm machinery were refusing to sell repairs in order to force the farmer to purchase new machinery. It is scarcely necessary to state that such malicious tales have been traced down and the farmer convinced of their falsity.

Farmers Badly Advised

The farmer has been badly advised in many parts of the country. He is literally to-day a very miserable person and reminds us of the old adage, "If you wish to be miserable you must think about yourself, about what you are, what you do, what other people think of you, and then you can be as miserable as you choose." The winter months have given the farmers too much opportunity to discuss their troubles with their neighbors. They have fed each other discontent. They cannot see why wholesale prices of mercantile commodities have been reduced 64 per cent and retail prices have only fallen 14 per cent. Farm production has been cut over 40 per cent in many products during the past eight months.

The farmer is thinking financially to-day as he never did before. He is comparing the cost of farming with horse and tractor more than in the past. He is also figuring the cost of raising a bushel of wheat or corn more closely than formerly. Herein is a clue to tractor sales—a clue advised by farmers at the Columbus show, and a clue agreed to by many manufacturers.

Tractors as Production Aid

The sound method of selling tractors is on the basis of an increased yield per acre due to tractor cultivation as compared with horse cultivation, and the shorter time necessary for such. In short, it is production farming. An Illinois farmer, Francis Mann, with 42 years farming record behind him, is authority for the statement that selling a tractor on the basis of cultivating an acre of ground by tractor as compared with horse is unsound, and detrimental to the general advance of tractors. He recommends selling a tractor on the increased yield in bushels from an acre of grain and the shorter time the ground can be cultivated with tractors and the ability to do this cultivation when it produces best results. An agricultural university after investigating tractors declared that farmers with tractors in that territory were plowing the soil 2 in. deeper than with horses, and the yield was 25 per cent per acre greater. This yield was partly due to deeper plowing, and partly due to the plowing being done when the soil was benefited most by the cultivation. It is well known that statistics over a period of 20 years show that there is a greater yield of winter wheat per acre in Kansas when the land is plowed late in July or early in August than if plowed late in August or in September. In July the soil is hard and dry and the temperature 110 Fahr. It is good tractor plowing weather but impossible horse plowing weather.

Similar conditions apply in regard to other crops and in other states in varying degrees. In Illinois corn planted before May 15 invariably yields more per acre than if plowed after that date. Several Illinois farmers have declared that it is impossible for a successful farmer to maintain enough horses to care for the spring plowing peak, and get the work done when it should be done. Here is another chapter on production farming. What is needed most for the tractor manufacturer is to largely revise tractor selling arguments to farmers and discuss the effect on soil and crop fundamentals and sell tractors on the basis of increase in production made possible by these factors. Sell the farmer tractors on a basis of ability to produce more bushels per acre at a lower cost per bushel and not on how much it costs for kerosene to plow an acre as compared with how many bushels of oats horses consume and how many pounds of hay are required to plow the same acre. To-day the farmer will not be slow to tell you that a bushel of oats is not worth more than a gallon of kerosene. You will find it a poor sales argument. The farmer must be sold the tractor as a production machine, one that does the farm work quicker than horses, does it better than it can possibly be done with horses, does the work when it should be done, giving more in return for effort expended, and permits the farmer to cultivate more land and produce a greater yield than is possible if he uses horses.

Production Per Man High on American Farms

The American farmer has a 5 to 1 advantage and greater producing value than the European farmer. In this country the average farmer cultivates 50 acres. In Europe he cultivates five acres. It is true the yield from European soil is twice that of our soil, but a little mathematics will demonstrate that even with the yield doubled our farmer cares for ten times the area of his European cousin, and with only 50 per cent yield he still is producing five times as much per person as the European. Tractor farming on a production basis is going to increase this yield, and give our farmer a still greater advantage.

In spite of what the world says our farmers have been making gains. In 1850 our farmers raised only 4.75 bushels of grain per capita. To-day they raise 9.2 bushels per capita. Improvements in farm machinery have largely contributed to this increase, but it must not be forgotten that since 1850 the agricultural valley of the Mississippi has come under the control of farming and the possibilities of production are greater there per man than in that part of the country further east cultivated in 1850. Our task is to increase still more the number of bushels per capita which the American farmer can raise. To do this it is not so much a problem of stopping the drift from the farm movement and encouraging a movement back to the farm, so much as increasing the producing capacity of the man on the farm. Those countries where agricultural population is greatest and where farming might be described as most intensive produce much less grain per person than the American farmer. Production in our factories has been stepped up by production machinery and production methods rather than by increasing the number of workers. Let us apply the same policy to agriculture.

Enormous Increase in Value of Farm Products

Some recent figures shed light on the value of the 1920 American crop and give an indication of the financial stability of the farmer. In 1920 the total value of farm products, which included grains, live stock, dairy products, cotton, wool, etc., was 100 per cent greater than the value in 1914. These figures are based not on the high price levels of July, 1920, but on the lower levels of 1921. In 1919 the total value of farm products in this country was $19,856,000,000. In 1920 it was

$5,000,000,000 above this. With these figures in mind and with the further fact that since 1914 the farmer has enjoyed unprecedented prosperity it is possible to arrive at a sane reason as to why the farmer will come back into the market when he completes his winter hibernation and gets busy with the work of the year.

The farmer is not being treated so severely on the price situation as he imagines. From 1913 to 1918 inclusive the price of farm machinery advanced 72 per cent. During this period the price of all other commodities sold to the farmer advanced 97 per cent. During this period the price of all farm produce sold by the farmer advanced 118 per cent. During this same period labor advanced 115 per cent, and freight rates increased 100 per cent. In his winter season of discontent the farmer has forgotten many of the advances of the last six years and has failed to get the correct perspective. He argues that the increased cost of labor was responsible for his present troubles. He should bear in mind that 60 per cent of all farm labor is tractor or horse and 40 per cent man. Investigations have also revealed that there has not been so much hired help on the farms because it was not available, except in 1920.

The Columbus Tractor Show

As a display of tractors, tractor parts, and power machinery to go with the tractor, the exposition was truly national and an unqualified success. As a national show for farmers or consumers it was not successful but merely a local show for Ohio farmers. An investigation of one bulk of 500 farmer registration cards selected at random from those received at the registration booth showed that 95 per cent of the farmers lived in Ohio.

As a national show attended by distributers and dealers it was not a success. A majority of the dealers attending were from Ohio and adjoining states. On the opening days, Monday and Tuesday, following the close of the Chicago motor car show practically all the dealers that registered at Columbus were present. From that time the dealer attendance fell off almost precipitously, indicating that perhaps a large proportion of those dealers attending were at the Chicago motor show and stopped off at Columbus on their homeward journey. It is a matter of regret that there should have been such an excellent display of tractors and parts and machinery, filling seven buildings at the fair grounds, and yet such a poor attendance of distributors and dealers both of whom are needed in the tractor field.

Chicago Ideal for National Show

You cannot hold a purely national tractor show except in Chicago or New York City. Chicago is first choice. The best time is the week of the Chicago motor show or if not then the week following. During the Chicago week there is the greatest gathering of dealers of any place during the year. Chicago has two buildings large enough to house the tractor show, the Municipal Pier, which has now been brought literally into the heart of the city by the widening of Michigan Avenue north to join Lakeshore Drive together with the new bridge construction and also by the erection of the Drake Hotel on the lake front. Dexter Pavilion in the Union Stock Yards is another possible exhibit space.

We are not going so far here when we suggest a national tractor show for New York City. New York City is the front door of the country through which a goodly part of the world enters. It is very largely our shipping door for export trade. As our export trade develops, as the bankers are determined it shall, and as our economists say it must, a tractor show in New York City would carry an international character and bring buyers from the shores of the seven seas. New York City offers the ground for a close introduction of the tractor to financial and business interests.

It is doubtful if at any future national tractor show there will be such a representative display of many tractor components, not a few murmurings of discontent having been heard from several exhibitors at Columbus. Many of these parts and component firms did little business, and several were asking the reason why they should attend a tractor show when they do not find it necessary to attend the national motor vehicle shows. In the formative days of the motor car industry they were at the national shows but during the past ten years their representation has constantly dwindled and the motor shows have become more exhibits of motor vehicles.

Were the national tractor show held during the motor car show week in New York these parts makers from headquarters at hotels could serve the entire tractor clientele as they do the motor car and motor truck clientele at present. The tractor industry is capable of making a very comprehensive display without these parts people. The exhibit at Columbus was almost too big. It resembled some of the tractor demonstrations held two or three years ago at which 90 or 100 tractors lined up across the end of a square mile of prairie and by the time they had finished plowing you had scarcely opportunity to walk across the field and had not enough opportunity to critically observe many of the machines. Seven buildings at the Columbus Fair Ground filled with equipment was representative of our agricultural prominence but was a hard task on the visitor who wanted to spend one day at the show. A more useful display would be one of the tractors and power farm equipment compactly placed side by side in one large building. This could be accomplished in the Municipal Pier or Dexter Pavilion, Chicago. The absence of two score or more parts makers would detract very little from the value of such an exposition. Nobody can say that the value of the motor car show fell off when many parts makers withdrew years ago. Such a national show should be conducted by the National Implement & Vehicle Association. It is the proper organization and the show is one of its legitimate activities.

Industrial Use of Tractors Increases

The Columbus show furnished a good initiation into the vastly increased use of tractors in industry outside of agriculture. It amazed some tractor manufacturers to find developing fields for creeper and wheel types in road-building, lumber camps, petroleum areas, mining sections and in other industrial uses. Naturally, the creeper type is practically dominant in these fields or most of them. Holt has gone almost entirely into the industrial field. Best, from California, found an unexpectedly great industrial demand at Columbus, one that greatly exceeded the agricultural demand. It has been known for several years that Cletrac has been one of the most active in developing the industrial uses and recent sales to municipalities and industries have been witnesses of the success of the policy. The enormous road-building programs are appealing to tractor manufacturers, as are snow removal and municipal uses.

The Columbus show gave evidence of a crystallizing movement in the tractor manufacturing field. While formerly there have been upwards of 70 tractor manufacturers at the national shows, this year there were fewer than 50. A few were kept away because their tractors are more suitable for areas West of the Mississippi than

east of the Mississippi, but the majority of those absent were absent because of financial stringency. In some cases companies have arrived at the conclusion that perhaps they are not national from a distribution standpoint. This reduced attendance gave indication of a possible mortality during the next year, a movement which has been under way in the motor car field for several years.

Another trend of the industry which has assumed prominence during the past year is the widening list of models of tractors furnished by not a few of the manufacturers, following a policy adopted years ago by several of our strongest truck manufacturers. Thus J. I. Case T. M. Co. has four models which serve the needs of a farmer using from two to twelve plows.

The presence of half a dozen makes of motor trucks intended for farm use gave a new interest to the tractor show and gave proof of the purpose of many tractor manufacturers to furnish their dealers with a complete line of farm equipment. During the past year such tractor manufacturers as Case, Avery, Wallis, Rumely, Moline, Twin City, Samson and some others have developed farm trucks. These were all on exhibition with the tractors and farm equipment machinery. Two firms, Graham and Atlas, exhibited trucks only.

The majority of these trucks are of the 1, 1¼, 1½ and 2-ton sizes especially designed for farm work. Most of them are fitted with pneumatic tires, although some are not. The question was frequently raised during the show as to whether these farm trucks fitted with pneumatic tires of a size larger than 5 in. might not meet with premature destruction due to the average ruts on country roads and in farms being made by a 5-in. tire. If such were true then there would be premature destruction of tires of 7 and 8-in. section.

Dealer the Weak Link in Merchandising

The dealer is still the weakling in the chain of power farming merchandising. He does not measure up to the needs of the hour. Too often he is a poor salesman, a poor financial man, and too unfamiliar with what tractor service means or must consist of. Just at the moment he is an especially weak and inactive link in the chain. Nearly every tractor manufacturer is looking for good dealers and not a few are in search of good distributers. The old time implement dealer with his warehouse shed near the railroad depot, has, as an active tractor dealer, almost passed out. Service was too incomprehensible to him, and when tractors became numerous the factory discovered it could not through its branch houses give the service which the dealer was the logical person to give. To-day a dealer is measured by his capacity to give service, and whether he is known as an exclusive power-farm dealer, an automotive dealer, or a general dealer, the yardstick that the manufacturer must use in estimating his ability is calibrated to measure service. The dealer must have three qualifications, ability to give service, ability to sell, and ability to secure the necessary financial support.

Tractor manufacturers are still unsettled, and divided as to the field in which the best dealer is found. It is only natural that such firms as Fordson, Cletrac and Samson, originating from the motor field, should largely put the selling and maintenance in the hands of motor dealers, some of whom have given up motor car sales and launched exclusively in the tractor fields. Whether they have done this or not they bear the stamp of the motor car dealer and have his conception of service and sales. Fordson went very largely last August to the Ford dealers. Samson has swung largely to Chevrolet, Buick and other General Motors dealers. Cletrac has many distributors from the car and truck field and for dealers they are looking for men who can qualify in service, sales and finance. In many sections they are largely automotive. The eventual dealer irrespective of what he may be called, must qualify according to the three requisites mentioned. Some tractor manufacturers are convinced that the exclusive tractor dealer is best, and cite average of sales per dealer proved their case. Others frankly admit that the dealer problem is still an unsettled one, and that they do not care from what source their dealers are recruited provided they can meet the requirements of the hour.

An Economic Commission Needed

What is needed most is that tractor manufacturers better educate their distributers and dealers on the fundamentals of tractor sales. Each distributer should know the soil conditions in his distribution area, and his dealers should be familiar with the character of soil cultivation that produces greatest yield in bushels per acre cultivated. The distributor and dealer should sell tractors on the production farm basis rather than on the relative cost of cultivating by horse or tractor. Agricultural colleges in many sections have the necessary information to enable merchandising tractors on a sound economic basis. The manufacturer should get this to the distributer and the distributer instill it into the dealer. To-day is the time when tractors must be sold on a basis of production ability. Intelligent farmers admit that while the dealer in the past has not sold them the tractor on this basis that they have purchased it on such a basis. Let us sell the tractor the easiest way. It is useless to start general propaganda to the farmers on how to buy tractors without first getting to the distributer and dealer the fundamental arguments.

The appointment of an agricultural engineering economic commission in connection with power farming might prove one of the most constructive steps that manufacturers could take. In the transition from operating a farm on an animal power basis to a mechanical power basis many considerations must be kept in mind.

As they are to-day many farms are not divided in the most suitable way for power farming. The division in the field has been arrived at on the basis of animal power farming.

Already there are some farms with too much mechanical equipment, witness a northwest farmer on 250 acres, with two tractors, two motor trucks, six stationary gas engines, one houselighting equipment and two motor boats.

It may be necessary for the farmer to erect a miniature factory with his power generator coupled to line shafting so that his belt work is concentrated, and his mechanical power furnished as efficiently as in a large factory. Our production factories with a centralized power house are recent creations. We would not mark the efficiency of a factory very high that had one power unit for each department. Yet this is what some farmers have been buying.

Closer co-operation of all those manufacturers producing machinery for the farm is necessary, so that an economic equipment of desirable machinery is obtained. That farmer is the nation's best asset who is correctly equipped with power machinery for the work to be done. If he is oversold he becomes a liability. If he is undersold he has not reached his possible production capacity. It might well be the work of an agricultural engineering economic commission to act in advisory capacity in this work and stimulate the necessary research.

An Engineer's Impressions of the Tractor Exhibit

By P. M. Heldt

SOME very good merchandising features were in evidence. The Bates Machine & Tractor Co. repeated its success at Kansas City last year. The Kansas City picture was a plowing scene, depicting a rural home for a background and a Bates Steel Mule tractor with plow on a platform laid with furrowed sod in the foreground. At Columbus, this company showed a tractor fitted with a snow plow, at work upon a snow-covered platform and in the background a painting of a rural winter landscape. A canopy was rigged up over the platform, supported a mechanism producing an artificial snow which fell in large light flakes in front of the painting, in close imitation of the real article. The picture was a pleasing one, but it did not attract as much attention as the plowing scene last year, which indicates that the farmer is concerned more with plowing than with snow removal.

Tractor chassis and power units on revolving stands were numerous. While the scheme of thus presenting a more or less complicated mechanism is excellent, it has lost somewhat as a drawing card as its adoption has been extended. The Cleveland Tractor Co. showed one of their Cletrac tractors with the chain track extended on the floor, an attendant slowly moving the tractor back and forth over the track by hand to demonstrate its easy running qualities. As at previous shows, the Heider friction tractor was again being maneuvered on a pair of planks on the floor, to demonstrate the ease of its control.

At the stand of the Allis-Chalmers Company, where three models of tractor were exhibited, demonstrations of the quick demountability of the engine were given at different hours of the day and always caused a considerable crowd to collect. The engine was placed on a stand on an elevated platform for the purpose, and the demonstration could be readily followed from some distance.

At the International Harvester Co.'s stand there were service booths at which instruction on ignition service and on the lubrication of the concern's tractors was given for the benefit of dealers and service men.

Moving Exhibits

Many of the exhibitors had tractors mounted on elevated platforms so that they could be conveniently inspected by visitors. Most of these show specimens—for they were specially finished in almost every case—were being turned over by electric motors, so as to help the salesmen in explaining their operation.

The most notable of the new designs were models brought out to extend or complete an existing line. This applies to the new Hart-Parr, Case, Twin City, Bates, Allis-Chalmers and LaCrosse. These new tractors in almost every instance embody all the features of previous models of the respective makers, and are merely reductions or magnifications of these earlier models.

Three Foreign Tractors

Three foreign tractors, the Somua, Fiat and Renault, were exhibited for the first time in this country, but are not new to readers of AUTOMOTIVE INDUSTRIES, as all of them have been illustrated and described in our columns. The Huber Mfg. Co. exhibited the Huber "Super Four" in addition to the Huber Light Four, manufactured for several years, the principal change in the new over the older model being that the former has a Midwest engine.

A tractor exhibited for the first time, and also quite out of the ordinary in several respects, is the Hicks, which is to be manufactured by the Hicks-Parrett Tractor Company—a recent merger of the Hicks Tractor Company of Milwaukee and the Parrett Tractor Co. of Chicago Heights, Ill. The company will be located at Chicago Heights and will continue the Parrett tractor in addition to the new Hicks.

Another new model so far as visitors to the national tractor shows are concerned was the Once Over Tiller made in Minneapolis. This machine, which combines a tractor with a plow and a pair of revolving soil millers or pulverizers, was developed by the Scientific Farm Implement Company. The Somua French tractors were shown in two sizes, one corresponding in power to an ordinary three plow tractor and the other to a garden tractor, the latter being of the soil miller type. It carries at the rear a drum which carries a number of prongs of spring steel and is rotated at a rapid rate by a positive drive from the transmission of the tractor. The drum can be raised and lowered at will and it is claimed that the soil can be loosened to a depth of 10 inches, if desired.

New Garden Tractors

Many of new models were to be seen in the garden tractor class. There are some machines made now which take the place of the ordinary hand cultivating tools often used in the home garden. These are very similar in appearance to the hand-operated cultivator, comprising a single wheel, a pair of handles, cultivating tools suitably connected to the frame of the implement and a small gasoline engine set on the frame and geared to the single driving wheel. As human muscular power is the most expensive form of power in common use, these little machines should prove highly economical wherever there is sufficient work for them to do.

An inspection of the show with respect to mechanical tendencies and developments does not convey the impression that the experimental departments of the tractor manufacturers were very active last year. It is, of course, generally known that sales have not been brisk lately, and the general impression is that considerable stocks of completed tractors have accumulated, which must, of course, be disposed of before anything new can be brought to the attention of the public. On the other hand, several of the leading manufacturers have well-developed, standardized lines and are hardly likely to upset their manufacturing routine by radical changes in design.

The changes in existing models which have been made and entirely new models brought out, point to the conclusion that the automobile type of construction will prevail; that is, the tractor with a four-cylinder engine, cut gearing, enclosed drive, anti-friction bearings and divided axle steering.

Anti-friction bearings are coming into extensive use even on the older style of tractors, and one of the most frequently heard sales argument for a tractor is that it contains so many ball and roller bearings. To judge by present tendencies, it will not be many years before it will be impossible to sell a tractor of two-plow size or over that does not have ball or roller bearings throughout except in the engine. It is therefore no wonder that the anti-friction bearing industry has become a powerful factor in the tractor industry, ball and roller bearing manufacturers being very conspicuous at the tractor shows and demonstrations.

It seemed last year at Kansas City that henceforth farm light outfits would form an important part of the tractor

show, but this year there was a decided retrogression in the representation of farm lighting sets, only three or four of the seventy or more sets on the market being shown. None of the farm lighting manufacturers allied with some of the big tractor makers, like the Sunnyhome Electric Co., the Domestic Engineering Co., and the Willys-Overland Co. exhibited. Whether this is due to non-solicitation by the show management or to a conviction that people who attend the show are interested primarily in farm tractors and not in lighting sets, is an open question. Owing to the slight competition and the large farmer attendance, the few makers of lighting sets which were represented should reap excellent results from the show.

There was again an excellent line of stock engines for tractors shown, including the Waukesha, Wisconsin, Hercules, W-S-M, Weidely, Climax, Stearns and Midwest. The LeRoi Co. had space at the show, but owing to delays in transportation no exhibits were on hand. While there was thus quite a variety in engines from which the tractor builder might make his selection, there was this year only a single transmission exhibit, that of the Nuttall Gear Company. Among the parts exhibitors, manufacturers of carburetors and ignition appliances were prominent.

Ignition appliances in connection with tractors means, of course, magnetos. Reference was made above to merchandising features in connection with complete tractors, and something should be said of merchandising features in connection with parts. In this respect the magneto manufacturers were easily the leaders among parts exhibitors. Several showed magnetos in operation under glass domes with a current of fine dust or a spray of water constantly playing on the magneto, to demonstrate its dust-proof and water-proof qualities. The K-W Magneto Company demonstrated two magnetos from which two of the magnets had been removed, being turned over slowly by means which were not apparent to the eye. One of the magnets was suspended from tubular posts by two chains and the other was mounted on a platform resting on a tubular post, which latter was sectioned to show that there were no wires running up inside. No wire connections could be seen on the outside, yet the magnetos kept turning at a slow, uniform rate and generating sparks, and the method of driving them was the cause of considerable speculation among technical men.

Final Drive Tendencies

In final drives there seems to be an increasing tendency to use a worm and wheel for the first reduction and a spur on internal pinion and wheel for the second. Among others, the new Farquhar has this form of drive. It combines the advantage of simplicity with efficiency, owing to the favorable working conditions, as the worm need not be subjected to excessive tooth pressures.

In the new Uncle Sam 12-20 model both the transmission and the final drive are by roller chains. The chains being completely enclosed and running in oil, the conditions of operation are, of course, much better than when exposed chains are used. Owing to there being two chain drives in tandem, and also two in parallel, it is quite difficult to provide means of adjustment, and none are provided in this case. The familiar "stretching" of exposed chains, which calls for frequent adjustments, is due to wear of the links, and in order to minimize this, unusually large chains are used. This experiment of introducing enclosed chains running in oil for tractor drives will be watched with interest by tractor engineers. The enclosed chain has not proven very satisfactory on motor trucks, but it must be remembered that on a motor truck it is much more difficult to enclose a chain, owing to the fact that spring play must be provided for.

Moving pictures showing tractors doing various kinds of work were another of the show attractions. One film illustrated the use of the Holt Caterpillar in logging work in Oregon and proved of great interest to the visitors, most of whom evidently were entirely unfamiliar with this class of work. The room in which the pictures were shown was entirely too small to take care of the crowds.

Descriptions of New Tractors Exhibited

Case 40-72

The J. I. Case Threshing Machine Co. showed for the first time a 40-72 hp. tractor on modern lines, and now has revised its whole line, which consists of four models. The new 40-72 hp. machine follows the other Case designs in having all the transmission shafts parallel with the engine crankshaft, and using open gears only for the transmission of power to the rear axle. All other gears are inclosed and run in an oil bath, which is a new feature for a tractor of this size. Engine, transmission and rear axle housing are separate units, which are bolted down to the channel steel frame by means of turned bolts. The frame consists of 8-in. and 10-in. channels, hot riveted. At the point of greatest strain the 8-in. channel is carried underneath the 10-in. channel, the two being reinforced by a 3/8-in. plate 18 in. deep, which is riveted to both. The 8-in. channels are extended to carry the platform and wheel guards.

The four-cylinder engine has 7 x 8-in. cylinders and runs at a governed speed of 750 r.p.m. Operating on kerosene it develops a maximum output of 90 hp. Two speeds are provided, 2.07 and 3 m.p.h. Characteristic of the robust construction is the 4-in. crankshaft, which has 4 x 4¼-in. crankpin bearings and main bearings of the following dimensions—4 x 7⅜ in. next to the belt pulley, 4 x 5⅜ in. at the opposite end and 4 x 5½ in. at the center. The length of the pistons is 9 in. The piston pin bearings measure 2 x 3½ in. Valves are 2¾ in. in diameter and have a lift of ½ in. Connecting rods are 17 in. long or more than twice the length of the stroke. The camshaft has a bearing diameter of 2¼ in. and the total length of its three bearings is 13½ in. The width of the cam face is 1⅛ in.

Pressure lubrication is employed, the oil being forced directly to the main bearings, camshaft bearings and crankpin bearings. A gear type of pump furnishes the pressure; it is driven by helical gears from the camshaft and is submerged in oil in a depression of the oil pan. The crankshaft is drilled for oil feed to the crankpins. An adjustable relief valve is provided, as well as an oil pressure gage, which latter is located in direct view from the driver's seat. A four-lead pump delivers fresh oil to the cylinder barrels at all times. A circumferential groove is cut in the cylinder liners so that the oil thus fed will be distributed all around the cylinders.

The belt pulley is mounted directly on the crankshaft. It measures 19½ in. in diameter by 10 in. width of face. A double disk type of clutch is fitted and serves to control both the belt power and the driving power.

The cylinders are cast in pairs and are fitted with renewable liners. Each pair of cylinders has a separate removable head casting. These head castings contain the

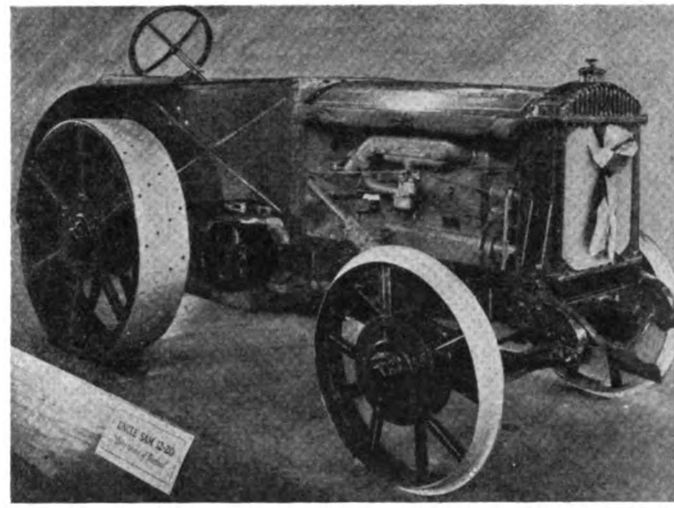
valves and the spark plug holes. A truck type of radiator, without soldered joints in the tanks, is fitted. Behind the radiator is a gear-driven fan in a fan shroud. The centrifugal water circulating pump is located in an accessible position. The differential gear is of the spur type, which is claimed to possess decided advantages for large powers, as it develops no side thrust and no thrust bearings are required in the differential. The differential is mounted on the bull pinion shaft, which is 3½ in. in diameter at the bearings, each shaft being supported by two Hyatt heavy duty bearings. The bull gears are 42 in. in diameter by 4 in. face and have cut and hardened teeth of 1¾ in. diametral pitch. These gears are inclosed in dust proof housings.

The rear wheels are 72 in. in diameter and 20 in. wide and are mounted on a 4-in. live axle rolled of special stock. This axle is carried in two Hyatt roller bearings. The front wheels are 48 x 10 in. and are mounted on Timken roller bearings. The Case 40-72 Tractor has a wheelbase of 124 in., an overall length of 200 in., a width of 105 in., a height of 110 in. and weighs 21,200 lb.

Once-Over Tiller

The Once-Over Tiller is a new form of farm implement that prepares a seed bed in one operation. It combines a tractor with a pair of plow bottoms and a pair of revolving implements, one at the side of each plow bottom, which break up or pulverize the soil as it is being turned over. The concern making this machine was formerly known as the Scientific Farm Implement Co., but in June, 1920, was reorganized as the Once Over Tiller Corp. The machine somewhat resembles the motor plows made in several European countries, in that the plow is combined directly with the tractor. There are two front driving wheels and one rear trailing wheel, and the engine overhangs the front wheels a considerable distance. The power plant consists of a Stearns four-cylinder 4½ x 6-in. engine, the equipment including a 1¼-in. Stromberg carbureter and a Splitdorf magneto with impulse starter. The transmission is of the company's own design and manufacture and is of the sliding gear type, giving three forward speeds and one reverse. The three forward speeds are 1¾, 2½ and 4 m.p.h., the intermediate speed being the plowing speed. All gears are cut and heat-treated, are inclosed and run in a bath of oil. The final drive is through internal gears, which are also inclosed. Both ball and roller bearings are used in the transmission and on the axle. The differential gear can be locked when desired.

The rotors on which the tilling knives are carried are driven from the tractor engine through a separate clutch and a pair of universal joints. The tiller gears are cut from carbon steel, case hardened and inclosed in an



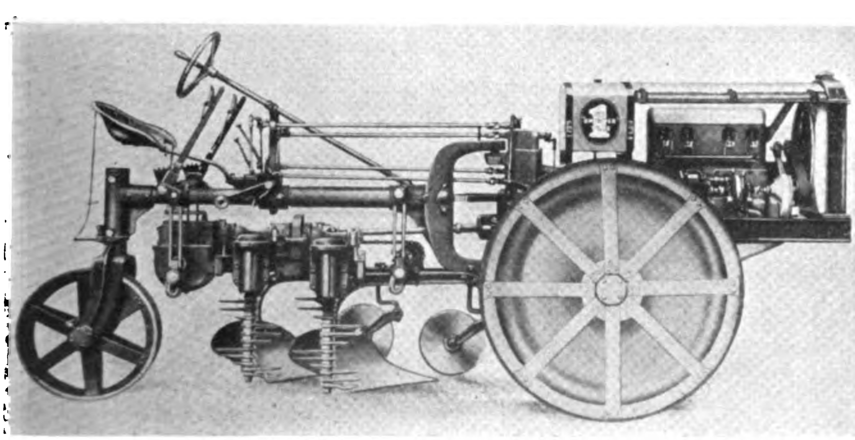
Uncle Sam 12-20 tractor

cil-tight case. The shafts of these gears are mounted on Hyatt heavy duty bearings. The knives of the rotor are made of crucible steel; a spring arrangement is provided which allows large stones to pass the knives without damaging the machine. A standard two-bottom Vulcan gang plow is used. It is lifted by a special mechanism, which is operated by the power of the engine directly instead of through the plow wheel. This makes the lifting mechanism positive.

Steering the Once-Over Tiller

Steering is by a rack and pinion mechanism and the driver's seat and controls are mounted on the tube extending back from the steering yoke. All controls of both the tractor and the plow are within easy reach of the operator. Ordinarily steering is accomplished by means of the hand wheel, which swings the driving wheels to one side or the other relative to the rear structure. But when it is desired to make a specially short turn, the operator can make the rear wheel a caster wheel by pulling a trip, and then by applying a brake to the front wheel on the side to which he wants to turn, he can make the machine turn on its own axis, it is claimed.

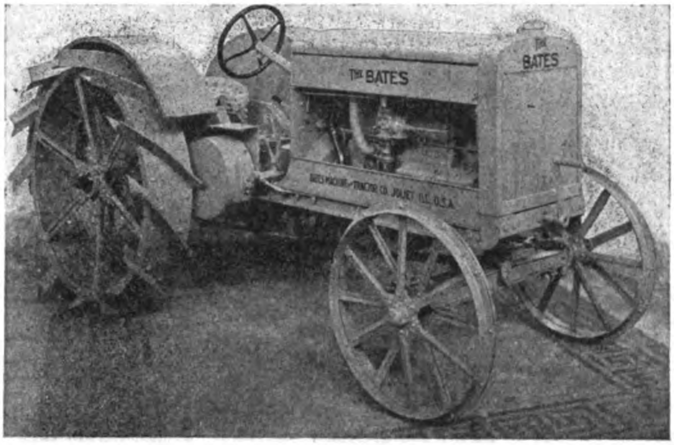
Following are some of the more important dimensions of the machine: Wheelbase, 116 in.; overall length, including plows, 196 in.; total width, 65 in.; total height, 75 in.; minimum ground clearance, 24 in.; drive wheel dimensions, 54 x 10 in.; belt pulley dimensions, 13 in. diameter by 7 in. width of face. The belt pulley is driven at 900 r.p.m. and is controlled by a Twin Disk clutch.



Once Over tiller

U. S. 12-20 Model

The U. S. Tractor & Machinery Co., which heretofore has specialized on its 20-30 tractor, has added a 12-20 model which embodies quite a number of features not found in the 20-30. It is an assembled machine in so far as it has a stock engine, but the transmission is of special design and is made by the U. S. company itself. The engine is a Weidely and is mounted at the front in the usual way. Cylinder dimensions are 4 x 5½ in., and the governed speed is 1200 r.p.m. A Bennet air cleaner and carburetor are fitted and ignition is by a Splitdorf magneto with impulse starter. The transmission is by a pair of bevel gears to a first



Bates wheel tractor

cross shaft, then by one or the other of two roller chains to a second counter shaft and then by another roller chain to the rear axle. The entire transmission is inclosed in a cast iron case and runs in an oil bath, and it is claimed that, owing to the fact that the chains are always well lubricated and protected from dust, they do not wear and stretch. Timken roller bearings are used throughout the drive and on the front axle as well. The front axle is of the automobile type and carries the frame on a semi-elliptic spring. The frame is built up of 4-in. steel channels. The belt pulley, which is located in a convenient position ahead of the drive wheel, is 14 in. in diameter and has a 6 in. face. It is equipped with a separate clutch and can be run in either direction. One of the features of equipment is a bucket seat similar to that furnished on the Uncle Sam 20-30. The machine is rated to pull two plows under all conditions and weighs 3000 lbs. Its two forward speeds are 2½ and 3½ m.p.h. The drive wheels measure 45 x 10 in. and the front wheels, 34 x 5 in.

Bates Wheel Tractor

The Bates Machine & Tractor Co. has added to its line a wheel tractor. The new model is identical with the older one from the front back to the rear axle. The Bates company has adopted the Midwest engine. The rating is 15-25 hp. engine, clutch housing and transmission are bolted rigidly together, forming one solid block which is mounted on roller-bearing axles. The transmission affords two forward speeds, 2 1/3 and 3½ m.p.h. The drive wheels are 48 x 10 in. and the front wheels 30 x 4½ in. The over all dimensions are: Length, 131 in.; width, 63 in.; height, 60 in. The tractor complete weighs 4000 lb. One clutch operates both the tractor and belt pulley and is controlled by a hand lever. This pulley is 16 x 6½ in. and gives a belt speed of 2450 ft. per min. All bearings of the transmission and axles are Timken. All gears are machine cut and run in oil. Although the engine and transmission case are bolted together, the frame is not dispensed with.

Hart-Parr 20

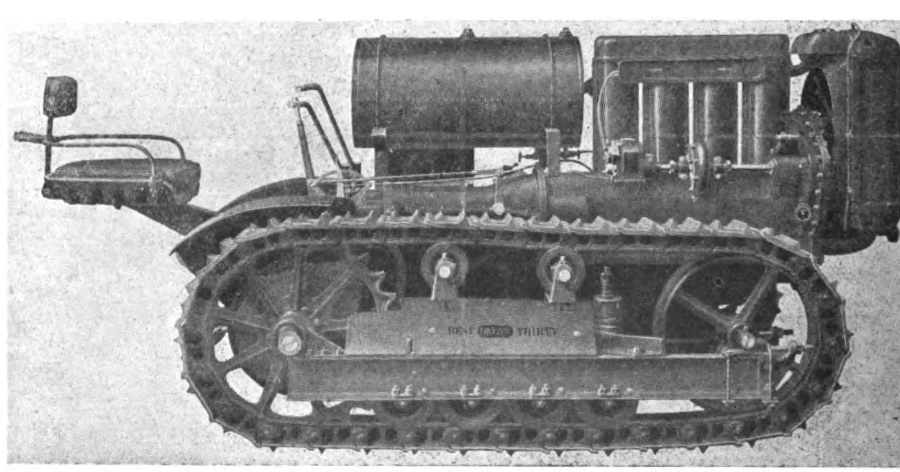
Heretofore the Hart-Parr Co. has had only a single model of 30 belt hp. rating. Now a 20 hp. model has been added. This is a replica of the earlier model on a smaller scale. The two cylinder engine has a bore of 5¼ in. and a stroke of 6½ in. and the tractor is rated to pull two 14 in. bottoms. Both cylinders are in one casting and the valves are in the head. The crankshaft main bearings are 2½ x 4 in. and the connecting rod bearings, 2½ x 2¾ in. Lubrication is by a mechanical oiler with six leads. A float feed carburetor in combination with the Hart-Parr shunt is used, and the tractor is designed for operation on kerosene. Ignition is by high tension magneto with impulse starter. The clutch is a Hart-Parr contracting band type and the transmission is of the selective sliding gear type furnishing two forward speeds, 2 and 3 m.p.h. All transmission shafts run on ball bearings. The drive wheels are 46 x 10 in. and the front wheels, 28 x 5 in. The frame consists of a single steel casting which is heat-treated. The machine measures 120 in. in length over all and 66 in. in width, has a tread of 62 in. (measured from outside to outside of wheels) and a shipping weight of 3500 lb.

Best 30 Track-layer

A very modern looking type of track-layer tractor is the Best 30 of which the first machine completed was exhibited, according to report. Engine, clutch housing and transmission are bolted together into one unit which is spring-supported on the track-layer frame not far from its center of gravity; so that nearly the whole weight is sprung. The engine is a Best four-cylinder, valve in head type with separately cast cylinders and a single removable head casting. The cylinder dimensions are 4¾ x 6½ in. An inclosed centrifugal governor is fitted and governs the engine at 800 r.p.m. Lubrication is by pressure from a gear pump. The Ensign gasoline carburetor is fitted and ignition is by high tension magneto. The piston pins are floating. The crankshaft is 2⅝ in. in diameter and the camshaft, 1¼ in. The cooling fan is gear-driven through a friction clutch.

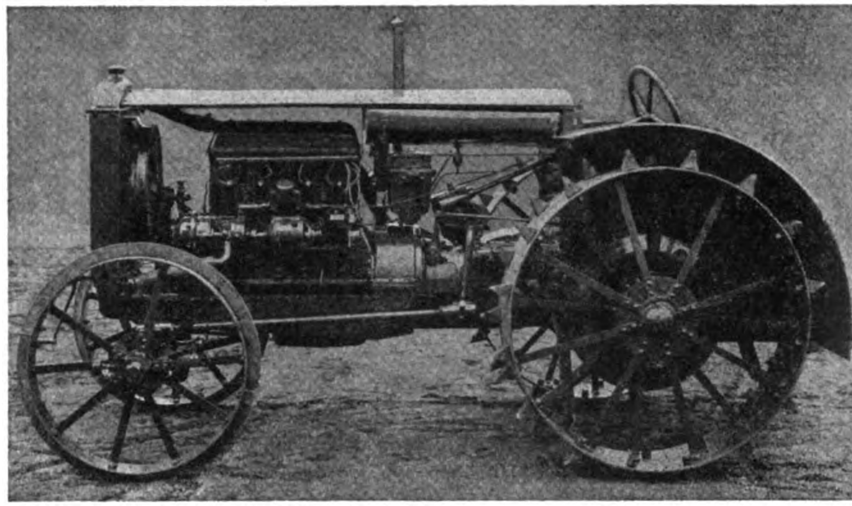
Steering is effected by applying power to one truck only by means of a large multiple disk clutch operated by long levers extending transversely across the frame. The trucks are spring-mounted, each oscillating independently of the other. Hardened steel rollers mounted on roller bearings carry the tractor. The track center distance is 41¾ in., the standard equipment consisting of 11½ in. shoes with a track length of 61 in. The track links are drop-forged and heat-treated. A double flanged front idler contacts with the spools of the track. The final drive is through 3½ per cent nickel steel, cut and hardened gears which are inclosed and operate in oil.

The total length of this tractor is 112 in., the height to the top of the radiator, 59 in.; the over all width, 53¼ in., and the width inside the tracks, 30¼ in. The ground clearance is 11½ in., the draw bar height, 16½ in. and



Best "30" tracklayer tractor

the ground pressure, 5.2 lb. per square inch. A 12 x 7 in. pulley is provided, which at 800 r.p.m. gives a belt speed of 2513 ft. p.m. The tractor carries 28 gal. of fuel (either gasoline or distillate, though kerosene equipment can be furnished as an extra). The weight of the tractor is 7400 lb. An upholstered seat with spring-supported, upholstered backrest is an attractive feature of this machine.



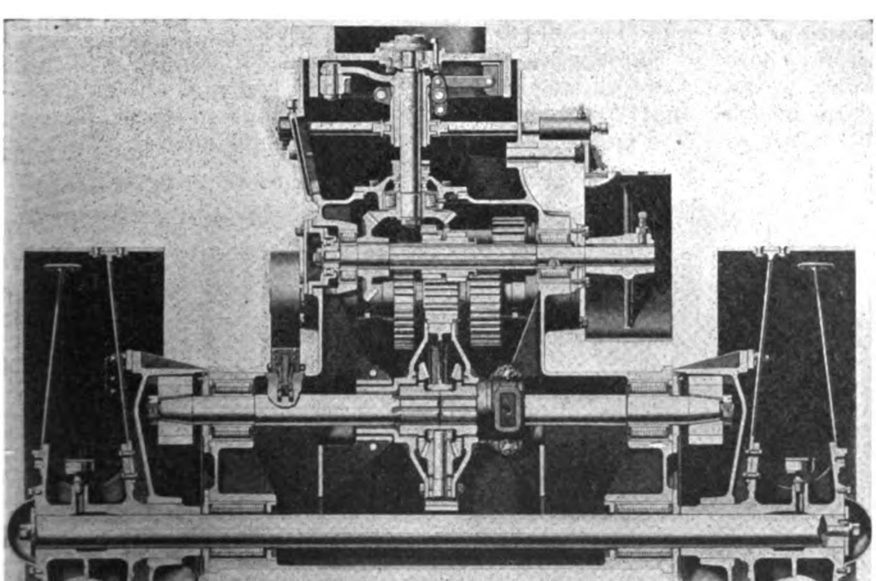
Allis-Chalmers 12-20 *tractor*

Allis-Chalmers 12-20

The Allis-Chalmers Co., which heretofore has been manufacturing a four-plow 18-30 and a single plow 6-12 model, has just added an intermediate size having a 12-20 rating. This machine is of the frameless type and is, of course, completely manufactured by the Allis-Chalmers Co. This concern has evidently decided to get out a full line of farm tractors and become an important factor in the tractor field. At the show a demonstration was given several times a day of the rapidity with which the Allis-Chalmers engine can be taken apart and reassembled, the former operation requiring 10 min. and the latter 15 min., more or less. Needless to say, the two mechanics making the demonstration worked rather harder than the average garage mechanic doing work on an hourly charge basis, and seemed to be about "all in" after the demonstration.

The new tractor model has a four-cylinder engine of 4⅛ in. bore and 5¼ in. stroke, governed to 1100 r.p.m. by an inclosed centrifugal governor. The engine is designed to run on gasoline and a supply of 20 gal. is carried in a tank over the transmission. A siphon type air washer cleans the air before it enters the carburetor. Fuel is fed to the carburetor by gravity. Lubrication is by pressure. The clutch is an expanding type and the transmission gives two forward speeds and one reverse. These speeds are 2½ and 3¼ m.p.h. The final drive is by inclosed internal gears, and a non-locking differential is fitted.

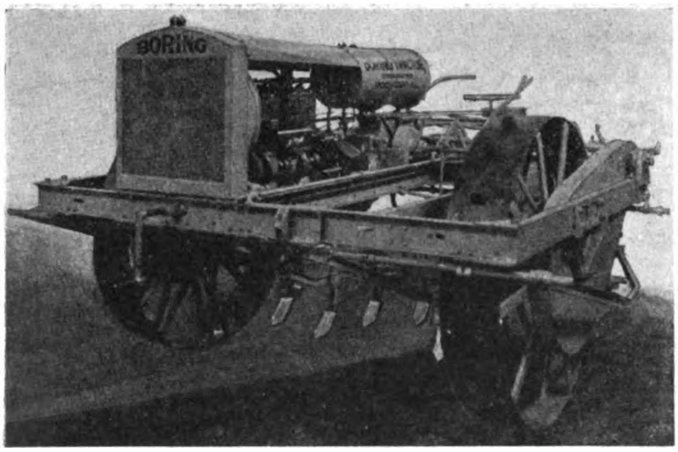
The belt pulley measures 12½ in. in diameter by 6½ in. face and the belt speed is 3250 ft. p.m. The same clutch that is used for driving controls the belt power. A brake is provided to act on the belt pulley. Following are some of the more important dimensions of this tractor: Total length, 135 in.; total width, 66 in.; total height, 60 in.; wheel base, 78 in.; minimum ground clearance, 13 in. The net weight of the tractor is 4400 lb. The clutch is operated by a hand lever at the driver's left and the brake pedal is located adjacent to this lever. The front axle is in the form of a casting of hollow section and is pivoted to the engine crankcase at the front, the gear case cover being extended to form a yoke for the axle. Radius rods extend from the ends of the front axle to a balance lever at the forward side of the flywheel bell housing. A spring keeps the fan belt automatically under tension. One-half of the bell housing is cast with the lower and one-half with the upper part of the crankcase. A bracket mounted on the transmission housing supports the steering column and the control levers.



Transmission and rear axle of Allis-Chalmers 12-20

Boring Convertible Tractor

The Boring tractor is somewhat different from the ordinary run of tractors in that it is a combination tractor and cultivator having a ground clearance sufficient to permit it to pass over corn 35 in. high, and having an adjustable wheel extension which will permit the machine to span two rows of corn. As a tractor the machine pulls three plows. It is of the three-wheel type having its two driving wheels at the front and a caster wheel used for steering located at the rear. When plowing and cultivating the implements are always in front of the operator, being located between the front and rear wheels. By means of the frame extension the wheel tread can be varied, from a minimum of 54 in. to a maximum of 79 in. This is accomplished by turning a crank located on the front cross member of the frame. The rear caster wheel is operated by a conventional steering gear enabling the tractor to be turned in a radius of 7 ft. The drive wheels are 54 in. in diameter and are 10 in. wide. The power plant consists of a four-cylinder 4⅜ x 5¾ in. Waukesha engine. This engine has a hollow crankshaft for force feed lubrication. The transmission has two speeds forward and one reverse. The high gear gives a normal plowing speed of 3½ miles per hour. A Bennett carburetor is fitted and it is claimed that



Boring convertible tractor-cultivator

the tractor can be run on either gasoline or kerosene. A Bennett air cleaner is used, this being of the centrifugal type. The power take-off is on the right side of the tractor and on the outside of the frame. It is independent of the engine clutch and the pulley turns only when the belt power clutch is engaged. Its speed is 41/100 that of the engine. The tractor weighs 3400 lb. and of this weight 3000 lb. rests on the front drivers and 400 lb. on the rear caster wheel.

Farquhar Three-Plow Tractor

A. B. Farquhar, the implement maker, this year exhibited a four-wheel tractor rated as a three-plow job of 15-25 hp. The tractor is assembled from well known units including a Buda engine. The drive is through an intermediate shaft to the transmission, which is located over and slightly back of the rear wheel axis. The tractor is steered and operated in the conventional way. The final drive to the rear wheels is through completely inclosed spur gears. The power plant of this tractor is a four-cylinder 4½ x 6 in. Buda engine located longitudinally. A K-W magneto is used for ignition. The carburetor is of Kingston make and two fuel tanks are provided, one for 5 gal. of gasoline and the other for 25 gal. of kerosene. An air preheater is located back of the engine just over the bell housing. Engine speed is controlled by a Pierce governor, operating normally at 900 r.p.m. A Borg & Beck clutch is located within the flywheel housing and is completely inclosed. A short shaft driving through two Hartford universals connects to the Timken-David-Brown worm gear first reduction. Two forward speeds are provided through sliding gears. These gears, together with the worm and worm wheel, all operate in an air tight oil bath. The cross shaft of the transmission is fitted with pinions meshing with drive wheel bull gears.

Steering is by a worm and wheel mechanism. The spark and throttle levers are located on the steering post center. The belt pulley is accessible from the driver's seat, and is driven by a chain. The driving wheels are covered with large fenders and no moving parts are within reach of the driver's feet. The tractor weighs 5700 lb. Its overall length is 162 in.; its width, 67 in. The wheel base is 83 in. and the ground clearance, 12 in.

The Hicks Crawler Tractor

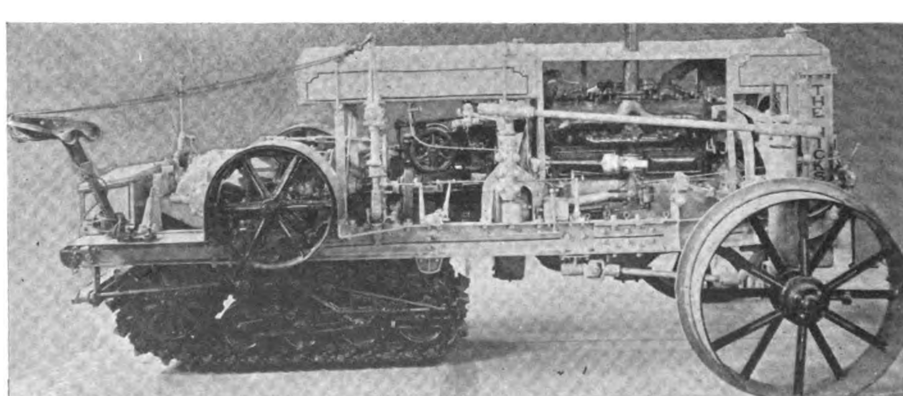
The Hicks is of the combined wheel and crawler type, having two front wheels for steering and two chain tracks at the rear for driving. The engine is a Buda four cylinder 5 x 6½ in. running at 800-900 r.p.m. Either gasoline or kerosene can be used as fuel. Fuel feed is by gravity, and ignition by a high tension magneto with impulse starter coupling. Engine speed is controlled by a fly-ball governor. A radiator of the built-up type is located at the forward end of the tractor. The transmission is of novel design, it is claimed, comprising cut gears of alloy steel whose shafts are mounted on annular ball bearings. All of the gears remain in mesh constantly and operate in an oil bath. Two forward speeds may be had, namely, 2.4 and 3.4 m.p.h. There are two chain tracks which are centrally located and are flexible in a vertical direction to allow for unevenness of the ground. These chain tracks are driven through a centrally located drive gear, both track sprockets being keyed to the drive gear shaft.

One of the most interesting features of this tractor is its steering mechanism. Steering is effected by engine power through a set of three bevel gears. The driven bevel gears are loose on their shaft but can be made to turn therewith by means of two cone clutches. These clutches are controlled by means of the driving lines. In order to start the tractor when the gear is in the neutral position, the driver gives a slight jerk on both lines. A pull on either of the lines turns the front wheels. There are two belt pulleys, one on each side of the tractor. These pulleys are controlled by expanding clutches. The overall dimensions of this tractor are as follows: Length, 132 in.; width, 78 in.; height, 72 in. The tractor complete weighs 7850 lb.

La Crosse Line-Drive Tractor

A small tractor with the line drive feature was shown by the La Crosse Tractor Co. This model has a 6-12 hp. rating and weighs in the neighborhood of 3000 lb. It will pull two bottoms, and the manufacturers figure that it will take the place of five horses under average horse working conditions. It has been hooked up with practically all implements that horses now handle, and one of the selling arguments put forward by the manufacturers is that it is not necessary with this tractor for the farmer to buy special equipment. In addition to the line drive this tractor has friction drive, which, however, is not of the disk and wheel type but consists of a friction roller which is adapted to engage with either of two concentric friction drums, one giving a forward speed and the other the reverse.

The engine has two horizontal cylinders of 4 in. bore and 6 in. stroke. It has two ball bearings on the crankshaft and reinforced die-cast bearings on the crank pins. The valves are located in the cylinder heads and are in-



Hicks tractor with power steering

closed. The front wheels turn on steering knuckles operated by the lines. Differential brakes are automatically applied by the steering mechanism and the applying mechanism can be adjusted to put these brakes on when the steering wheels have been swung around through any desired angle. There are only two speed reductions from the engine crankshaft, first through the friction wheel and drum and then through a lantern wheel and internal gear. The latter is cast in eight sections.

Some New Garden Tractors Exhibited

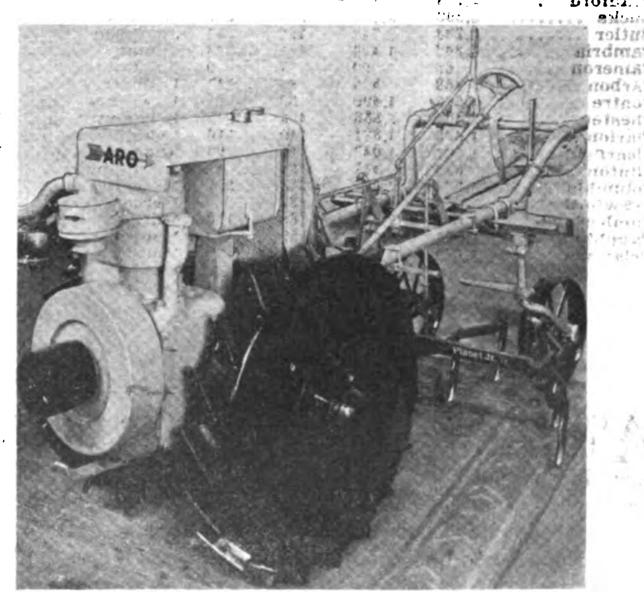
THE Spry Wheel, made by H. C. Dodge, Inc., is a single wheel tractor and cultivator combined. It has a frame 37½ in. long and 7 in. wide, with side members of pressed steel, on which is carried the single cylinder two-stroke air-cooled engine. The cylinder of this engine is cast with cooling flanges and is heat treated before the final grinding at a temperature of 1150 deg. Fahr., so that it will not warp after being finished. Two flywheels of semi-steel are keyed to the crankshafts, the crankpin being secured into their webs to make a built-up crankshaft. The piston, which is 2½ in. in diameter, is provided with three rings. A vaporizer is used instead of a carburetor, and ignition is either by a Bosch high tension magneto or a non-vibrating coil and three dry cells. The transmission is through a chain to the intermediate shaft and thence through a pinion and internal gear to the single 20 x 3½ in. drive wheel. There are two adjustable cast wheels toward the rear of the frame, and the tool carrying equipment, which is adjustable for various depths of cultivation, is suspended directly behind these wheels. The handles are bolted to the frame just forward of the drive wheel axis, and the one-gallon fuel tank is carried on them. The spark advance lever and ignition switch are located at the curve of the handles, and it is claimed that with these control devices alone a speed variation from 1½ to 4 m.p.h. can be obtained. The standard tool equipment consists of a 12 in. rear tool holder with adapter plates by means of which the tool spread can be extended to 18 in.

The Aro tractor is a machine designed to do any kind of one-horse job. Unlike most of the smaller machines so far made, it is a riding tractor. The power plant consists of a single cylinder 4½ x 5 in. engine running normally at 800 r.p.m. The crankshaft is 2 in. in diameter and is mounted in Hess-Bright ball bearings. The connecting rod bearing is 2¼ in. in diameter by 3 in. in length. Gasoline is used as fuel and a supply of 2 gal. is carried in the tank. Fuel feed is by gravity to the Schebler carburetor and ignition is by a high tension magneto. Lubrication is by splash, with circulation by a plunger pump, and the cooling water is circulated by thermo-siphon action. The flywheel is mounted at the front of the engines. A shoe type of expanding clutch is fitted. The belt pulley is on the flywheel and is 6 in. in diameter by 4½ in. wide. Transmission is through a worm and wheel, giving a single reduction between the engine crankshaft and the driving wheels. Worm and wheel are enclosed in an oil-tight case. The drive wheels are of the disk type, 30 in. in diameter by 4 in. wide. The width of tread can be adjusted. There are two 16 in. caster wheels at the rear. This tractor is 106 in. long over all, and 45 in. high; it weighs 1,000 lbs. and is rated as a 3-5 hp. machine. Its speed can be controlled between limits of 1 and 3 m.p.h., and it is capable of pulling one 10 in. plow. The minimum ground clearance is 10 in., but under the axle the clearance is 12½ in. The operator steers the machine with his feet; he controls its speed with the throttle lever, and all movements of the tool are controlled with one lift lever. It is claimed for the Aro that with a 10 in. plow it will turn a full-width furrow of good depth under all soil conditions, operate disks, harrows or other seed bed tools and do a thorough job of cultivating any wide row crop, being readily adjustable to different row spacings.

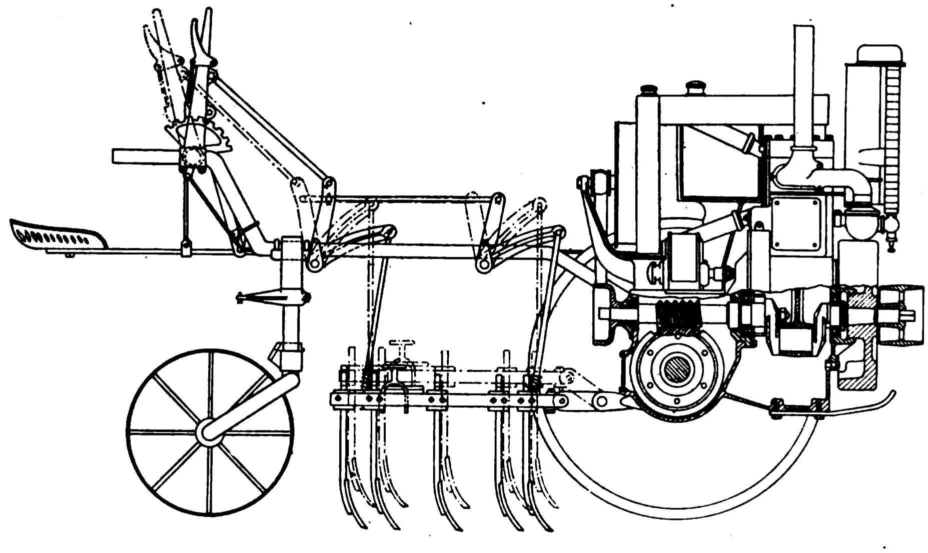
Another garden tractor shown for the first time is the Centaur manufactured by the Central Tractor Co. This has a single cylinder, vertical, air-cooled engine rated at 5 hp. Cooling is effected by means of a blower in the flywheel. Ignition is by a Bosch high tension magneto and lubrication by splash in the enclosed crankcase. The drive is through a pair of bevel and a pair of spurcut gears to a countershaft and thence through an enclosed chain to the driving axle. A differential gear is fitted on the axle, to make steering easy. The driving wheels are 28 in. in diameter by 4 in. in width and are spaced 25 in. center distance. The over-all height is 38 in. and the axle clearance 12 in. For plowing or for use on wet or sandy soil wheel extensions increasing the width of the drive wheel to 8 in. can be applied. The machine is started and stopped by means of a multiple disk clutch and its speed is controllable between the limits of 1½ and 3 m.p.h. There is a belt pulley on an extension of the crankshaft for such work as pumping, grinding and line shaft driving.

The Gromor cultivator was exhibited by the Frank Held Tractor Co. This machine has a single cylinder, vertical, air-cooled engine with an integral reduction gear of 8 to 1. From the engine shaft there is a chain drive to a countershaft with a reduction of 2 to 1 and then comes a final drive by gears with a reduction of 4½ to 1. This gives a total reduction of 72 to 1 and should make the machine sufficiently powerful to cope with all soil conditions. For cooling the engine, a four-blade open fan is mounted at the side of the cylinder driven by belt. Among the claims made for this cultivator are that it has a low center of gravity and sufficient clearance to make operation easy. Drive wheel, motor supports and bearings are of gray iron, while all other parts are of soft steel, cast steel or manganese bronze.

A number of changes in design have been made in the



Aro, one of the riding garden tractors



Sectional view of Aro tractor

trance into the cylinder. The shape of the combustion chamber has been changed somewhat and the compression raised 10 lb. p. sq. in. Removable valve stem guides and a variable speed governor are now employed. The magneto drive has been improved and the location of the spark plug so changed as to place it in the path of the incoming charge. The piston is now relieved eccentrically instead of all around and the connecting rod bearing is oiled by means of an oil ring catching oil, in addition to the oil it receives from the splash.

A number of improvements have been made in the Beeman garden tractor, the pioneer in its class. The crankpin bearing area has been increased. The clutch mechanism has been redesigned, so that both wheels

Utilitor tractor whereby the power of the engine has been materially increased. The engine has been retimed and the valve lift increased 1-16 in. At the same time the inlet manifold was enlarged so as to give the gases a freer en-

are positively released when the clutch is withdrawn, and the crankcase has been remodeled so as to give more room. There is now an oil reservoir or sump under the camshaft gears.

Fifty-five Per Cent of Pennsylvania Farmers Own Cars

SEVEN out of every hundred farmers in Pennsylvania purchased automobiles during 1920, while at the present time, fifty-five out of every hundred farmers in the State own automobiles, not including farm trucks. These figures are shown in a table prepared by Statistician L. H. Wible, of the Pennsylvania Department of Agriculture.

More than 100,000 farmers in the State own automobiles, many of these owning two and three machines, while there are 14,325 farms in the State upon which motor trucks are in use. Lancaster county easily leads in the number of automobiles on the farms, this county having 7914 cars on its farms on January 1, 1921, while Berks county is second with 3836. Cameron county, with 90 automobiles, has the fewest of any in the State.

The following table shows the number of motor vehicles on the farms, January 1, 1921, based on the 1920 census figures which give Pennsylvania 202,298 farms, as compared with the number of January 1, 1920, which was based on the old census figures which gave Pennsylvania 219,000 farms:

British Authority Predicts All-Metal Plane in Future

ACCORDING to the *Morning Post* of London, Major-General Seely, Under Secretary of the State for Air, speaking recently at Cambridge at a meeting of the Air League of the British Empire, stated that: "Although great strides have been made in the science of aeronautics much remains to be done, and it is to Cambridge scientists that we must look for great service in this respect. The aeroplanes of the future must be of all-metal. The present method of wood construction is quite wrong where an internal combustion engine is used. Greater safety and greater comfort are needed. We are behind other nations in this respect, and the need is a very urgent one."

Many Subjects Discussed at S. A. E. Tractor Meeting

Entire day given over to professional sessions and dinner during tractor show at Columbus. Plowing and belt speeds, non-freezing solutions, alcohol fuel and tractor tests are among the subjects discussed.

By P. M. Heldt

A ONE-DAY program devoted entirely to tractor subjects was arranged by the S. A. E. in connection with the Columbus Tractor Show. The professional session was held at the Southern Hotel and was followed by a tractor dinner at the Deshler. The first item on the program of the professional meeting was a report by D. L. Arnold on An Investigation of Plowing Speeds. A variety of opinions was expressed during the discussion. One member said that the average farmer liked to travel fast, and the idea of high speed plowing appealed to him. He also said that there is no inherent difficulty in high speed plowing. When an ordinary traction dynamometer record is inspected it is observed that the draft varies constantly between rather wide limits. This fluctuation of the drawbar pull is due to a number of causes, one being imperfect scouring of the plow. It is true that the draft increases with the speed.

Plowing Speeds

Another speaker, coming from Massachusetts, where the ground is decidedly stony, said that he hoped high plowing speeds would not be attempted in his neighborhood. An experience was cited of a tractor which when plowing 4 in. deep would pull a certain number of plows, but when setting the plow deeper one more bottom could be pulled. This was due to wire grass in the soil. When the plow was set for deep plowing it cut below the wire grass.

O. B. Zimmerman said that the plowing speed problem is an intensely serious one. If the draft increases with speed there would be a great waste of energy, and, besides, the increased wear and tear on the machine must be considered. The scientific method of arriving at results which had been followed by Mr. Arnold should be of great value to the country.

John Mainland made a report for the Committee on Pulley Face Widths and Speeds. This consisted chiefly of a report on the work done by this committee during the past year, and as the recommendations of the Committee were adopted by the Standards Committee at the New York meeting, what he said was in the nature of a review of the work accomplished the past year. Mainland said that as an implement man he favored tractor pulleys 2 in. wider than the belt width, instead of only ½ in. wider as recommended, in view of the difficulty of accurate alignment of the tractor with the threshing machine, but realized, that in many cases it is difficult to get such a wide pulley on the tractor. He said that one width of pulley recommended was 4 in., and that this is entirely inadequate for threshing. He was later informed by another member that the 4-in. pulley is not intended for threshing but for such lighter work as feed grinding.

The Tractor Division of the Standards Committee during the past year adopted a recommendation to the effect that all tractors should be equipped with governors, and in this connection Mainland emphasized the importance of the governor in threshing. He said that the cylinder of a grain separator has a peripheral speed of 6,250 ft. per min.—a higher speed than the average flywheel rim, and that in four instances he knew of cylinders driven by tractor engines having no governor had burst due to excessive speed.

A paper on Anti-Freezing Solutions for Tractor Cooling Systems was read by O. B. Zimmerman. The author enumerated the qualities that must be possessed by a good non-freezing liquid. It must be cheap and easily obtainable; it must be non-corrosive and non-electrolytic. The specific heat should be as low as possible and the boiling point should not be too low. Table salt and calcium chloride are out of the question because of their electrolytic effects. Alcohol makes a good non-freezing solution, but owing to the fact that only the alcohol evaporates the operator is usually in the dark as regards the strength of his solution and its degree of safety.

Cooling Systems

Mr. Zimmerman spoke particularly favorably of the use of mineral oils in the cooling system, with which he had had practical experience on automobiles. One objection that has been made against the use of kerosene as a cooling fluid is that it gives off unpleasant odors, but this is of no particular consequence in connection with a tractor. The life of rubber hose in the cooling system, if kerosene is used, is from three months to two years. Some objection has also been raised to the use of kerosene on account of the fire hazard, but there is no record of a case of destruction due to this cause.

Mr. Secor of the Advance-Rumely Co. said that he fully agreed with what Mr. Zimmerman had said. There were some 50,000 Rumely tractors with oil-cooling system in service. The system, he said, is simpler than the conventional water cooling system, and the only attention required is the occasional repacking of the pump. The temperature of the radiator is higher at low loads than with water cooling. A somewhat larger pump is required than with water. The chief advantage of the oil cooling system is that the oil will not freeze. A cooling surface of 8 sq. ft. per b. hp. is allowed on tractors. The oil used is known as Winter black and has an initial boiling point of 550-575 deg. Fahr. The average temperature of the oil leaving the jacket is 175-200

deg. It rarely attains 225 deg. As a rule, the smaller the tractor, the higher the temperature that can be carried. There has been no trouble from jackets and radiators being clogged by the oil, and in general there have been no complaints in connection with the cooling system.

Mr. Arnold said that he had used kerosene in his automobile and had had no trouble with it. One hose lasted two years and another a year and a half. He expressed the view, however, that it could be used only with pump circulation, as a car with thermo-siphon circulation would quickly overheat when the cooling system is filled with kerosene, except perhaps in very cold weather.

Dr. Marshall of the Bureau of Standards spoke briefly on the principles underlying the design of cooling systems as developed at the Bureau particularly in connection with aircraft work.

At the afternoon session, Prof. Sjogren spoke on the tractor tests made at the Nebraska University. He presented a table giving the results of all tests made to date. Records of these tests have been published in AUTOMOTIVE INDUSTRIES. As is well known, quite a few tractors have had to be changed in one way or another before they could pass the tests, and in some cases the tests showed up defects of which the manufacturers' engineers knew nothing. Fan belts gave much trouble, and in some cases larger fans or larger radiators were installed. Sometimes there were indications that the water space around the cylinder head was too small, for the heads would overheat while the temperature of the outlet water was not excessive.

Air Washers

In a few cases heat control devices for the vaporising system were installed. Air cleaners of the dry type were often too small, and reduced the power of the engine unnecessarily. Prof. Sjögren said that air washers often proved ineffective because the farmer did not want to bother refilling them with fresh water and rather than do so took them off entirely.

It is desirable to be able to crank a tractor engine when the belt drive is in use. This is not possible with some designs. It was Prof. Sjogren's impression that ratings are being made on too narrow a margin. He also said that there is considerable diversity in the practice of rating. For instance, of three tractors fitted with the same engine (3⅛ x 4½ in.) one was rated as a 6-12 hp. at 1000 r.p.m., the second as a 5-10 hp. at 1000 r.p.m. and the third as a 6-10 hp. at 1200 r.p.m. Prof. Sjogren explained that in making the brake tests no allowance was made for losses in the belt. Prof. Magruder of Ohio State University thought that this method was open to criticism, as the loss in the belt will vary with the belt tension, and if the belt is crossed there is an additional loss. Prof. Sjogren answered that there is no easy method of making allowance for or determining the belt losses, and as the conditions were the same for all tractors, this was not considered necessary. An analysis of the results showed that two tractors developed less than 50 per cent of their belt horsepower at the draw bar, while the highest proportion of the belt horsepower developed at the drawbar was over 80 per cent. In the reports of the operators and observers it was stated whether the course of trouble was considered to be due to faulty material or faulty engineering, and both were found to be about equally frequent.

In Prof. Sjogren's report it was stated that 42 spark plugs were replaced during the tests, and this point was taken up by A. W. Scarratt, who gave it as his opinion that the fault was not with the plugs but in the design of the engine. He had found that out of 50 makes of spark plugs only three would not give satisfactory service in kerosene-burning engines of the type built by his firm. What is necessary, he said, is a little more attention to the design of the spark plug bosses and their cooling means.

Mr. Zimmerman asked what relation exists between the drawbar pull and the weight of the tractor. It was pointed out that this relation depends on the diameter and width of the wheels and upon the type of lugs used. The weakest link in tractor operations, Zimmerman said, was the hold on the ground. The plow must be designed to give a maximum disturbance of the soil with a minimum energy consumption and the tractor must be the direct opposite. He voiced the opinion that an enormous amount of power is lost between the crankshaft and the drawbar.

Mr. Scarratt read a paper on the Carburetion of Alcohol, which is reproduced almost in full herewith. Prof. Norman of Ohio State University said that he did not expect to see a sufficient shortage of petroleum fuel in this country for many years to come, such as to give a chance to power alcohol.

There are enormous deposits of oil-bearing shales in Colorado which give an oil very similar to Pennsylvania crude, and recently large additional deposits have been discovered in Tennessee. In Germany successful use was made of alcohol-benzol-kerosene mixtures, and it was found that very lean mixtures were required. Mr. Secor said that in his opinion alcohol would not interest the present generation, except insofar as it relieved us of any anxiety as to what would become of our children after the last drop of gasoline has been used up. His firm some time ago received a report of a test with alcohol fuel on an Oil-Pull tractor made for the Esthonian Government. No changes were made in the engine, which operated at 80-85 lb. compression, and the fuel consumption was determined to be 0.735 lb. per hp.-hr.

Replying to a question as to the practicability of working shale oil deposits, Mr. Peck said it had recently been proven that shale containing less than 20 gal. per ton had commercial possibilities. An oil field had recently been discovered near San Antonio, he said, which would supply us with oil for the next 300 years.

General Purpose Tractor

E. A. Johnston, chief tractor engineer of the International Harvester Co., spoke briefly on the subject of tendencies in traction design, and then showed motion pictures of an experimental tractor of which several samples had been built by his company. This is, perhaps, the most nearly universal machine that has ever been built. It is a three-wheeled type and was shown plowing, discing, cultivating, hauling wagons, operating self-binders, corn binders, corn huskers, seeders, a spraying outfit and hay machinery of all kinds.

In the discussion Mr. Johnston was asked how small a farm this outfit would be practical on. He replied that the horse eats the product of 5 acres and that this represents only 60 per cent of his total cost, so that he really costs as much as is obtained for the products from 8 acres. Usually 7 to 10 horses are kept on a 150-acre farm. Power apparatus can be operated at 60 per cent of the cost of horses. One of the advantages of a universal tractor with a set of specially designed implements as shown in the moving pictures is that a very material reduction can be made in the weight and cost of the implements. Some such development as that shown by the pictures, Mr. Johnston said, must be accomplished in order to reach the small farmer.

A representative of an electric lamp concern asked what were the chances of electric lighting coming into

general use on tractors, the same as on automobiles. Mr. Johnston replied that they were slight, so far as could now be seen. Night plowing was about as unsatisfactory as night work in the factory. There is always increased breakage, and the dew interferes to a certain extent with efficient work. The small farm is usually worked by the farmer alone, and he could not possibly work 24 hours a day. On the larger farms the equipment is usually adequate to make night plowing unnecessary. There is a slight demand for electric lighting equipment, but not sufficient to warrant the fitting of such equipment on all tractors.

Mr. Nash said that in California much night plowing is done, and usually by electric light. An outfit, which requires no battery and is suitable for two lights, has been developed by one of the large electrical companies. One of the most successful tractor owners works his tractors 22 hours a day during the season, six days of the week, and spends about one-half of the seventh day going over the machine.

Tractor Dinner Well Attended

The Farm Plow dinner was well attended. Fred Glover acted as toastmaster. The first speaker of the evening was J. B. Davidson, executive councilor of the American Society of Agricultural Engineers. Dr. Davidson quoted a noted Canadian to the effect that there are only three primary vocations, namely, agriculture, homemaking and education. He asked what made for a high standard in agriculture. Some people claimed that it was maintenance of soil fertility. If that was so then agriculture has attained its highest development in Korea, where fertility of the soil has been maintained for forty centuries. However, in Davidson's estimation soil fertility and plant breeding are not key factors in agriculture. There are 8000 fewer farmers in Iowa to-day than there were 10 years ago. The percentage of the agricultural population did not make for a high standard of farming.

He would align himself with that new school of economists who say that what we want is efficient agriculture. This is measured by capacity for production. The health of the people on the farm is a factor. Many of the operations on the farm are mechanical in nature. Thus, for instance, harvesting and carrying the products to market are mechanical operations. Thirty times as much grain is produced now as in 1830. Before the war 9,000,000 people in the United States produced as much grain as 66,000,000 in Europe. An enormous amount of power, aggregating 25,000,000 hp., is used in agriculture, far more, according to statistics quoted by Davidson, than used in the industries.

Engineer in Agriculture

Davidson said that there is a big field for the engineer in agriculture. There are in this country 200 million acres that can be reclaimed by clearing, 80 million acres that can be reclaimed by drainage and 150 million acres that can be reclaimed by irrigation. There is, therefore, no danger of a shortage of arable land. The farmer is thinking of two things just now; one is how to get more for his product, and the other, how to reduce his cost, and in this latter connection at least the engineer could be of great service to him.

The second speaker was L. J. Taber, Master of the Ohio State Grange. He said that the triumph of the century, which has changed barbarism to civilization, has been all the work of the engineer. For thousands of years agriculture was carried on in the same old way, but there has been a mighty change in the last half century. Power and farm machinery are closely interwoven. There is none of the radicalism among Ohio farmers that has made itself evident in other sections, and there would be none unless the financial and manufacturing interests failed to take heed of conditions in the country.

Farmers' Strike Result of Inexorable Conditions

Speaking of deflation brought us face to face with the subject of the so-called farmers' strike. The American farmer purchases 45 per cent of the manufactured articles that are not exported. There has been a 45 per cent decline in the value of farm products in the last six months. The condition referred to is not exactly a strike but simply the working out of inexorable conditions. The farmer cannot do without the things essential to efficient production. The great need to-day is the creation of a better understanding between town and country.

It is necessary to lighten the task of the farmer's wife. The farmer must have sufficient reward to enable him to put electric light into his home, to put in power washers and other labor-saving devices for the home. There can be no permanent prosperity in farm life while marketing problems are being neglected. We must have a proper co-operative movement among farmers, a community organization looking after the sale of farm products and the purchase of farm necessities on a co-operative basis. The farmer wants to become a businessman besides.

The last speaker was W. H. Stackhouse, President of the National Implement and Vehicle Association, who presented a good deal of statistical matter bearing on farm production and on the prices of farm products and other merchandise. Mr. Stackhouse said that in 1820 95 per cent of all the people of this country lived on the farm, whereas the percentage in 1920 was only 49. In 1849 the wheat produced in the United States amounted to 4.3 bushels per capita, while in 1920 it amounted to 9.4 bushels.

Farmers' Purchasing Power

According to Mr. Stackhouse it would be utter folly to deny that the world-wide business depression had not affected the farmer. The farmer's purchasing capacity is not the same to-day that it was a year ago. Within the last few days the Department of Agriculture has published figures showing that the value of all farm products in 1920 was $19,856,000,000, which is about five billion dollars less than in 1919, but it would be taking a wrong view of the matter to say that the farmer has lost this amount. The value of farm crops alone in 1919 amounted to $11,405,000,000. From 1913 to 1920 the cost of farm implements increased 78 per cent; the value of farm products, 112 per cent; the value of labor, 115 per cent, and the value of all other commodities, 144 per cent.

Referring to the reputed pressure on farmers to keep them from buying, Mr. Stackhouse said just because it's raining we need not think that it's never going to shine. The farmer wants the cost of manufactured products reduced, and he can be assured that just as soon as the replacement cost of manufactured articles is reduced the manufacturer will lower his prices. It would be folly for him to follow the suggestion to cut prices at once and shoulder the loss, as that would simply lead to a crop of failures. In concluding Stackhouse referred approvingly to the movement inaugurated by the Government during the war of causing the number of different items of manufacture to be reduced, and to the National Repair Week fathered by the National Implement and Vehicle Association.

The Carburetion of Alcohol

AT the tractor meeting of the S. A. E. held at Columbus on February 10, A. W. Scarratt, engineer of the Minneapolis Steel & Machinery Co., presented a paper on the above subject. Mr. Scarratt's firm is doing considerable business with South America and other foreign countries where petroleum distillates are very expensive. He mentioned Cuba, Brazil, Argentina, Chile, Porto Rico and Venezuela, where the introduction of tractors is hampered by the high cost of kerosene, while alcohol is produced in vast quantities and is comparatively cheap. Quoting Mr. Scarratt:

"Naturally, if American tractors are to succeed in these countries they must be equipped to operate on alcohol in an economical and efficient manner. Many manufacturers will claim that their engines will operate on alcohol, and they will, but in a very inefficient and wasteful manner because they are not primarily designed with a view to using this as a fuel. * * *

"The Minneapolis Steel & Machinery Co. has exported a large number of tractors in the past twelve years, during which time many of them have been required to operate on alcohol. But it is only in the last year that the demand for greater economy and efficiency when using alcohol has been seriously felt. During 1920 we have done some intensive studying and experimental work in the development of an engine which will burn alcohol economically and efficiently. * * *

"Alcohol is difficult to vaporize, hence difficult to start on; it ignites at a considerably higher temperature than gasoline, is only 6/10 as rich in heat units as gasoline by weight and is 15 to 20 per cent heavier by volume. Commercial alcohol contains approximately 10 per cent of water by weight and from 10,000 to 12,000 B.t.u.'s per pound, its specific gravity is from .80 to .84 at 60 deg. Fahr., and its range of distillation temperatures is from 158 deg. Fahr. to 175 deg. Fahr., and it is a vegetable derivative. These physical characteristics are quite different from the common petroleum fuels.

"We knew that higher compression was necessary, but as engine size and design influences operation to a large extent, our first problem was to establish an approximately satisfactory compression pressure from which to start our experiments. Our first trials were with 127 lbs. gage compression at normal operating speed. The next problem was to determine what amount of heat applied to the mixture was desirable and its general effect on economy, output and operation. Here we had a real surprise when we discovered that more heat is needed for good operation on alcohol than is required for using kerosene.

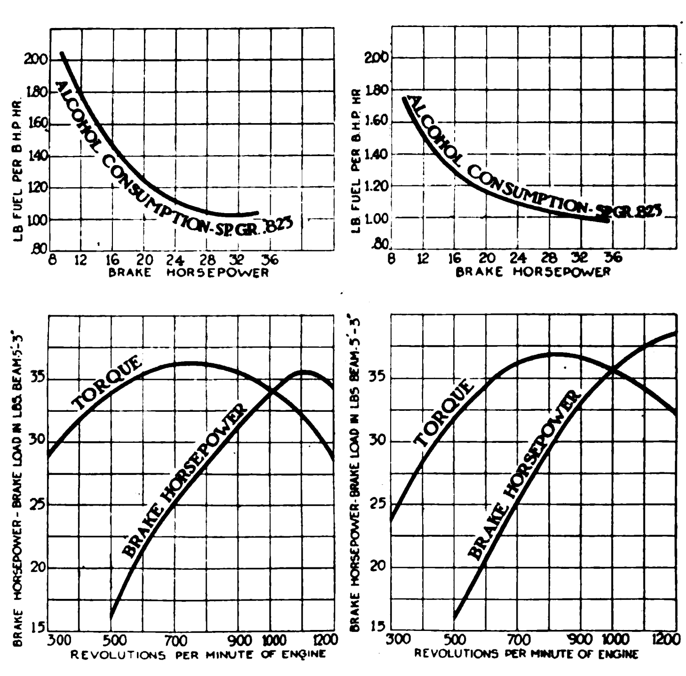
"Our next concern was in regard to the power output, which we found was equal to the power developed when using good kerosene. We then concerned ourselves with the general operation of the engine and finally with the fuel consumption. At first the operation was not good at low engine speeds when under sustained load, and the fuel consumption was higher than we liked, but by perseverance and patience we overcame these obstacles and produced very creditable characteristics with good economy and excellent operation and with two distinct and totally different types of carbureting and manifold systems, one of which was the special Twin City-Holley system worked out by our company and employed on all Twin City tractors at the present time, and the other was the Twin City vaporizer system.

"We felt that if we could obtain the same power with alcohol as with gasoline or kerosene for the same expenditure in B.t.u.'s of fuel, per b.h.p. developed, that we would be doing very well. As a matter of fact, we have exceeded these hopes slightly and actually show a fair increase in thermal efficiency.

"Our experimental work was done on a 4-cylinder 4¼ x 6 in. 16-valve engine. At first no heat was applied to the intake manifold and we were only able to develop 29 b.h.p. at 1000 r.p.m., using 127 lbs. compression, whereas we could easily develop 35 h.p. with kerosene, using 63 lbs. compression. When running with a cold manifold, the temperature of the intake charge dropped to 35 deg. Fahr., frost collected on the manifold and water froze on certain portions of it. It was necessary to choke the carbureter to a considerable extent and very unsatisfactory operation was the result. We then applied heat, with the result that the horsepower increased from 29 to 35 and operation was very much improved, although the engine would not pick up its load at low speeds.

"An intake manifold with glass inserts was used which showed that a large amount of wet, unvaporized fuel was going over to the engine. We then increased the heat still more, by connecting two air heaters for the carbureter intake in series. This dried out the mixture but decreased the horsepower from 35 to 33, although the fuel consumption was decreased considerably, being 1 lb. per b.h.p.-hour. With this set up, the inlet air to the carbureter reached a temperature of 210 deg. Fahr. but after being carbureted the intake gas temperature dropped to 138 deg. Fahr., with an exhaust gas temperature of 215 deg. Fahr. We then decided to drop our compression pressure to 100 lbs., with the result that nearly equal h.p. was developed, the fuel consumption was not increased and the operation was improved at low engine speeds.

"We then tried an intermediate compression, using 110 lbs., which was finally adopted as giving the most satisfactory results. With this compression we had no difficulty in obtaining an output of 35 h.p., which was equal to that developed when using kerosene, and fuel consumption at maximum load remained 1 lb. per



Power curves of Twin City 4¼ x 6 in. four-cylinder tractor engine running on alcohol with two different carbureters

b.h.p.-hour. The alcohol used in this experimental work contained 10,500 B.t.u.'s per pound. An equivalent gasoline consumption by weight would show a fuel consumption of approximately 0.55 lb. per b.h.p.-hour, which is exactly equal to the finest performance which we have obtained on this engine using gasoline and which is decidedly more economical than average engine performance indicates.

"The difficulties of starting are increased somewhat when using alcohol, due to the greater starting effort necessary for cranking the engine and also because air, at ordinary temperatures, does not vaporize the alcohol sufficiently to make a good combustible mixture. Satisfactory starting was accomplished by a redesign of the starting crank coupled with the use of a mixture of alcohol and gasoline, the ratio being four parts alcohol to one of gasoline.

"Following are a few of the important features which we believe necessary for the proper use of this fuel. In our case, 110 lbs. compression proved most satisfactory. Very liberal provision for heating the fuel charge must be made. Use of the entire exhaust heat will be found necessary. The temperature of the ingoing charge of fuel for good carburetion and economical operation should not be less than 100 deg. Fahr. Careful consideration should be given to the design of the intake manifold so as to obtain uniform distribution. At high compressions this is very essential, especially when using alcohol. Gas velocity is important. The intake manifold gas velocity, at full load, should not be less than 9500 ft.p.m. average.

"In our opinion, alcohol is an ideal fuel. It is completely distilled or vaporized at practically a constant temperature. This is a decided advantage and once the engine is properly warmed up, the operation is all that can be desired. There is practically no carbon residue created when using alcohol and the condition of the valves and valve seats, after long periods of heavy run, is surprisingly good.

"We are thankful that it was necessary for us to do this experimental and development work with alcohol. In our opinion the use of alcohol as a fuel, eventually is bound to come in the United States. We believe that the entire automotive industry should get behind this idea and bring it about as quickly as possible so as to provide another source of fuel supply and to bring down the operating costs of all equipment, depending now on hydro-carbon fuels. There are millions of tons of vegetable matter unused in the United States yearly from which alcohol could profitably be manufactured. If the manufacture of alcohol for fuel purposes is demanded by the automotive industry it will head the list of automotive fuels eventually."

AN interesting volume treating of the organization and management of trade associations has been published by the Ronald Press Company. It analyzes in detail the purpose, structure, procedure and value of the trade association and contains a very complete and accurate list of trade associations and their addresses. The book is written by Emmett Hay Taylor.

Safety in Spring Shackles

WRITING in *Engineering* on defective design in motor trucks brought out by war service, F. Strickland remarks that a point affecting the safety of light cars is the arrangement of the spring hanger of the front spring. With the usual arrangement of front springs the axle is attached to the frame only by the front part of the spring. A considerable number of springs broke, and if the fracture was between the axle and the front spring horn there was nothing to hold the axle except the rear shackle.

In the earlier days of motor cars the shackle was in tension, being hung from a bracket as shown in Fig. 1, following carriage practice. Later, however, the shackle was generally put in compression (See Fig. 2) as a bracket is saved and the appearance is neater.

In case the front spring breaks in front of the axle, the construction shown in Fig. 1 is in stable equilibrium while that in Fig. 2 is not. Further, in the first case the motion backwards is limited, while in the second the link may swing back to the position shown in dotted lines. In the latter case the motion of the axle is considerable, and the car frequently gets quite out of control. The result of this, in France, was a number of very serious accidents owing to the cars running off the road at speed. In order to avoid these a short length of belting was fixed under the spring at the spring seat and attached at the front in such a way as to prevent the axle going back in case of the spring breaking. While this belting was the usual method of securing the axle in the service there are neater ways of doing it.

Figs. 3 and 4 show two methods which were tried and found effective. In Fig. 3 two short lengths of angle iron bolted to the shackle formed stops so that in case of the spring breaking the motion of the shackle was limited. This proved effective and was easily adapted to the spring shackles of some cars. It was very cheap and easy to apply, requiring only two pieces of angle iron about 2 in. long, and one bolt for each front spring shackle.

Fig. 4 illustrates another arrangement, which was also very effective and not expensive. In this case a plate about ¼ in. thick is bolted to the frame. This plate has a slot allowing the necessary motion to the shackle, but preventing motion beyond this.

Means of Materially Increasing Thermal Efficiency

This article, though written with special reference to aircraft engines, contains extremely valuable suggestions applicable to other automotive types, and is worthy of careful study by all who desire to improve the thermal efficiency of these engines. The use of stratified charges and other means for improving efficiency are clearly outlined.

By H. R. Ricardo*

IN presenting this paper the writer aims to indicate certain possible lines of development and research which his investigations and preliminary experiments have shown to be at least worthy of serious consideration. If we review the present state of the art we find the position to be substantially as follows: From a thermodynamic point of view the performance of the modern aero engine has approached so nearly to the ideal obtainable from the cycle on which it operates that there is little scope for improvement. Thermal efficiency or fuel consumption is now the all-important factor, but since the best modern aero engines are actually developing a thermal efficiency within 4 per cent or 5 per cent of the highest obtainable from the cycle on which they operate, it is evident that to gain any further improvement it will be necessary either to depart from, or at least to take considerable liberties with, the accepted cycle, or to modify the composition of the fuel, or both. The cycle on which all present-day aero engines operate is one in which an explosive mixture of fuel and air is drawn into the cylinder compressed to the highest pressure permissible without detonation and ultimate pre-ignition, then ignited at constant volume and expanded until it occupies the same volume as before compression, after which it is released and the cycle is repeated. The theoretical efficiency of this cycle is given by the formula $E = 1 - (1/r)^{\gamma - 1}$. This is known as the air standard efficiency; it assumes that the specific heat is constant at all temperatures, that there is no loss of heat and that there is no dissociation. According to this formula the efficiency is dependent upon r, the expansion ratio. In the ordinary cycle r is also the compression ratio, since compression and expansion happen to be equal, but it must be remembered that it is the expansion and not the compression ratio which governs the efficiency, and that the two need not necessarily be equal.

The most recent investigations on the properties of the working fluid carried out by Mr. Tizard and Mr. Pye and corroborated by the writer's experimental results, show that when due allowance has been made for the losses due to change of specific heat and to dissociation at the temperatures which actually obtain in the cylinder, the true limiting thermal efficiency becomes approximately $E = 1 - (1/r)^{0.295}$. This formula takes no account of the losses due to the direct passage of heat to the cylinder walls during combustion and expansion. It is clearly impossible to arrive at a really universal formula which will take this into account, since the proportion of heat lost must depend upon the form of the combustion chamber, the speed, and, in fact, on the individuality of each engine. In the most perfect case of an engine having a compact and symmetrical combustion chamber and running at a high speed, so that the direct heat loss during combustion and expansion is reduced to the absolute minimum, the highest attainable indicated thermal efficiency is given pretty accurately by the formula $E = 1 - (1/r)^{0.25}$. This allows for the minimum possible heat loss to the jacket walls and may be regarded as the absolute limiting thermal efficiency obtainable under the best possible conditions, assuming:—

(1) Perfect carburation and distribution.

(2) That the compression and expansion ratios are equal.

(3) That the mixture is homogeneous and of the most economical strength.

The following table (Table I) illustrated by the curves in Fig. 1 gives, in column (1) the air-cycle efficiency for a range of compression ratios from 4:1 to 8:1, column (2) Tizard and Pye's ideal efficiency, taking into account losses due to change in specific heat at high temperatures and to dissociation, column (3) the highest attainable indicated thermal efficiency assuming that the combustion chamber is designed to allow of the minimum possible heat loss, that the cylinder is of comparatively large capacity and that the revolutions are not less than 1500 r.p.m. In column (4) are given the actual indicated thermal efficiencies as obtained in a special variable compression engine designed by the writer for research purposes, and in which every known artifice for obtaining the highest possible efficiency and power output has been employed.

TABLE I

Expansion Ratio	Col. 1 $E = 1 - (1/r)^{0.4}$	Col. 2 $E = 1 - (1/r)^{0.295}$	Col. 3 $E = 1 - (1/r)^{0.25}$	Col. 4 Observed Results Variable Compression Engine
4.0	0.4256	0.336	0.296	0.277
4.5	0.4521	0.359	0.314	0.297
5.0	0.4747	0.378	0.332	0.316
5.5	0.4944	0.396	0.348	0.332
6.0	0.5116	0.411	0.361	0.346
6.5	0.5270	0.424	0.375	0.360
7.0	0.5398	0.437	0.386	0.372
7.5	0.5534	0.449	0.396	0.383
8.0	0.5647	0.460	0.406	....

The difference between columns 3 and 4 indicates the scope left for improvement—it is very narrow. So long as the recognized cycle is adhered to, in its entirety, the importance of raising the compression and, therefore, the ex-

*From a paper read before the Royal Aeronautical Society of Great Britain, Dec. 1920.

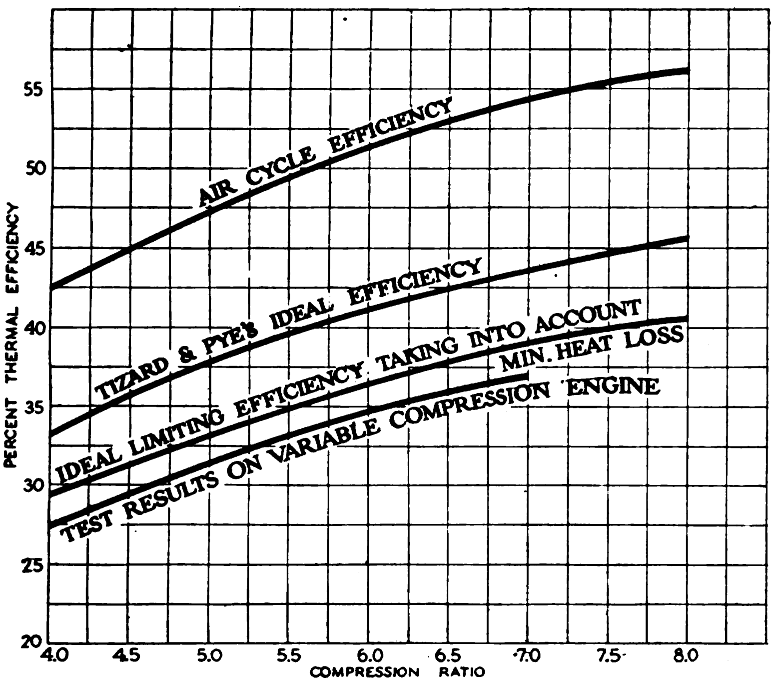

Fig. 1—Curves showing efficiencies with varying compression ratio

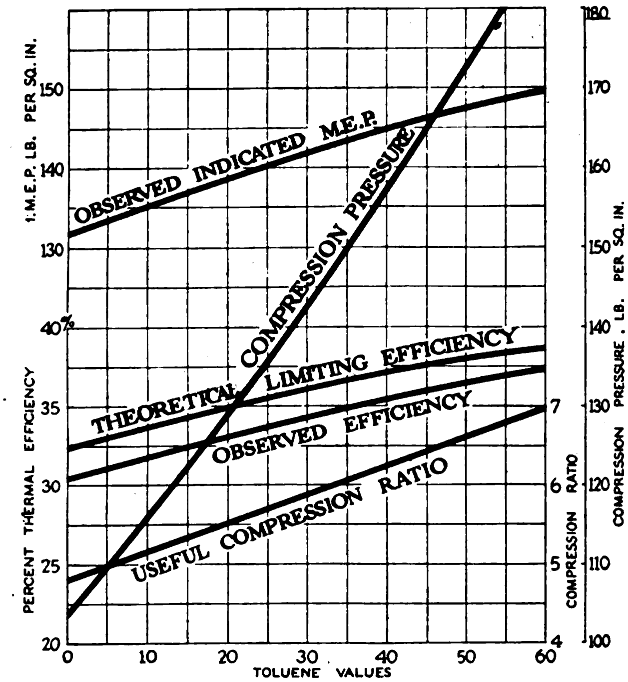

Fig. 2—Curves showing toluene values, compression ratio, efficiencies and observed I. M. E. P.

pansion is obvious. Now when working with all fuels belonging to the general group known as gasoline the compression pressure which can be employed is limited by the tendency of the fuel to detonate and ultimately to preignite. The explanation of the phenomena of detonation appears to be as follows:—When the mixture is ignited from any one point, the flame at first spreads by the normal process of flame propagation aided by turbulence and in doing so compresses before it the unburnt portion of the charge; unless the latter can get rid of its heat with sufficient rapidity, it is liable to be compressed to a temperature exceeding its self-ignition temperature, with the result that it ignites spontaneously throughout its whole bulk and an explosion wave is set up which strikes the walls of the cylinder with hammer-like blows, giving rise to the familiar noise known as "pinking." This explosion wave further compresses the portion of the charge first ignited, thus still further raising its temperature, and with it the temperature of the igniter points or any other partially insulated object in the neighborhood from which ignition first started, to so high a temperature as ultimately to cause pre-ignition and loss of power. Pre-ignition, which is the ultimate limiting factor controlling the compression, never occurs under normal conditions with gasoline, except as a result of persistent detonation. If detonation be prevented, a much higher compression can at once be used without any risk of pre-ignition, and a very decided gain both in power and efficiency obtained thereby.

There can be little doubt that detonation depends primarily upon the normal rate of burning of the fuel, and this in turn depends upon the pressure, and, to a less extent, upon the temperature at the time of ignition. If means be adopted either for slowing down the normal rate of burning or raising the self-ignition temperature of the fuel, or both, detonation can be kept in control and a much higher compression ratio can be used. Either or both of these methods are available. With the exception of ether, acetylene and hydrogen, fuels composed of light paraffin fractions have been proved to be the worst offenders as regards detonation—they are chain compounds and therefore chemically unstable, their ignition point is low, and their normal rate of burning very rapid. On the other hand, fuels belonging to the aromatic group, such as benzol, toluene and xylene are ring compounds of greater chemical stability and high ignition temperature, they cannot be made to detonate even with compression ratios as high as 7.5:1.

It has been known for a long time that by adding benzol to paraffin petrols the tendency to detonate could be greatly reduced, but recent experiments at the writer's laboratory have shown that of these three members of the aromatic group, benzol is the least effective and toluene the most, while xylene occupies a position midway between the two. On account of their relatively low heat value per pound, it is naturally desirable to employ as small a proportion of aromatics as possible. Of the three aromatics mentioned, benzol has also the highest specific gravity and the lowest heat value per pound. It is, therefore, from every point of view the least efficient of the three. Experiments on the variable compression engine have shown that the compression pressure can be raised in direct proportion to the aromatic content of the fuel. A light paraffin freed from aromatics and consisting mainly of fractions of the paraffin series, but conforming in every respect to the Air Ministry's specification for aircraft spirit, detonates under normal conditions as to temperature, etc., and with the most efficient mixture strength and ignition timing, at a compression ratio of 4.85:1 (the degree of compression at which detonation starts being very sharply defined). By adding 20 per cent of toluene the compression can be raised from 4.85:1 to 5.57:1, the gain in efficiency on actual test is found to be from 31.1 per cent to 33.5 per cent, and in mean effective pressure from 131.8 lb. per square inch to 140 lb. per square inch. Now the addition of 20 per cent toluene adds less than 2 per cent to the weight of the fuel per unit of heat and permits of an increase in efficiency of 7 per cent. The net gain is, therefore, very considerable. Finding toluene the most efficient medium for preventing detonation, it was decided to express the tendency of fuels to detonate in terms of their toluene value.

Starting with a light paraffin gasoline, freed from aromatics, the relation between toluene value and the highest compression ratio which could usefully be employed was

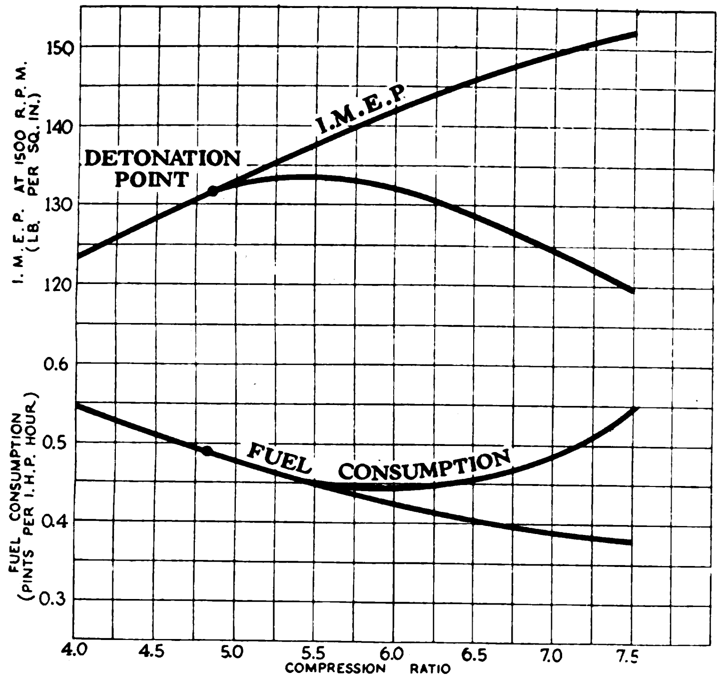

Fig. 3—Curves showing fuel consumption and I. M. E. P. with cooled exhaust gas

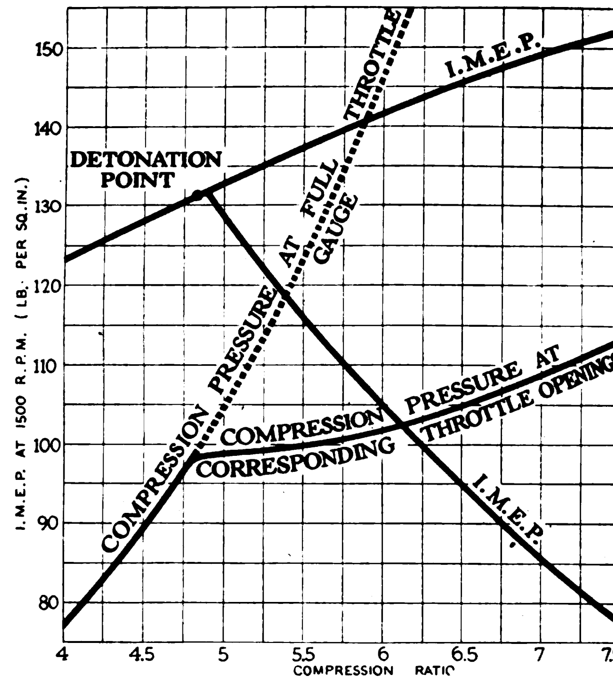

Fig. 4—Curves showing I. M. E. P. and compression pressure with varying compression and throttling

found to be as shown in the table, and the curves in Fig. 2.

Toluene Value	Compression Ratio	Ind. Mean Pressure as Found by Experiment	Ind. Thermal Efficiency as Found by Experiment	Limiting Ind. Efficiency
0	4.85:1	132.5	0.311	0.327
10	5.20:1	135.4	0.323	0.338
20	5.57:1	138.7	0.335	0.350
30	5.94:1	142.0	0.347	0.361
40	6.32:1	144.9	0.355	0.371
50	6.67:1	147.5	0.365	0.380
60	7.05:1	150.0	0.373	0.388

Toluene Value

Toluene	+	100
Benzine	+	66
Xylene	+	83
Ethyl-alcohol, 99 per cent	+	166
Acetone	+	75
Cyclohexane	+	30
Carbon bisulphide	+	10
Methyl mercaptan	+	5 to 10
Ether	—	60

Later investigations showed that toluene was not the most efficient dope, and that, in fact, it could not compare with alcohol, though this fuel is not likely to be of much value for aircraft on account of its low heat value per pound. The preceding table gives the toluene values of a number of different fuels.

From this table it will be seen that the fuel known as hectar, and consisting of 50 per cent benzol and 50 per cent cyclohexane, which the Americans have found so successful, therefore has a toluene value of 48, and could be used with a compression ration of 6.6:1.

It is well to emphasize the fact that of all the known volatile hydro-carbon fuels the total internal energy (taking into account the heat of combustion on the one hand and the change in specific volume on the other) is substantially the same, that is to say, when completely evaporated and used at the same compression ratio, all fuels, irrespective of their heating value, will give the same thermal efficiency and the same power to within about 2 per cent. The only exception is alcohol and the other members of its group; these, under normal conditions, give a slightly higher power because the increase of specific volume after combustion is very considerable, and also in practice owing to their higher latent heat they are seldom completely evaporated, with the result that a considerable amount of evaporation takes place in the cylinder during the suction stroke, thus both increasing the weight of charge and reducing the compression temperature. Popular theories that benzol or mixtures of benzol and gasoline give higher power at the same compression than pure gasoline, owe their origin to the fact that most engines have already too high a compression for efficient use with pure gasoline, with the result that a late ignition setting and often an over-rich mixture also must be used. The addition of benzol in such a case permits of the use of full ignition advance and the most efficient mixture strength, and so gives rise to this very prevalent impression. Actually the total internal energy of, and therefore the power output available from, benzol is very slightly less than gasoline.

Apart from varying the composition of the fuel, which is not always practicable, a somewhat similar increase in compression and therefore in efficiency can be obtained by the addition of inert gases which serve merely to delay the normal rate of burning. Experiments with pure aromatic-free gasoline of 0 toluene value showed that the safe compression ratio could be raised from 4.85 to 1 up to 7.5:1 by the addition of cooled exhaust gas. Fig. 3 shows the relation between mean pressure, thermal efficiency and compression ratio, when just sufficient exhaust gas was admitted in each case to check detonation. The upper part of the I.M.E.P. curve and lower part of fuel consumption curve show results obtained with a fuel of high toluene value and of the same total internal energy. The divergence between the two mean pressure curves indicates approximately the proportion of inert gas added. It will be observed that the compression ratio can be raised at once from 4.85:1 to over 6:1 without any reduction in power whatever, and with a very substantial gain in efficiency; thus it is possible to improve the economy of an engine by as much as 6 per cent without affecting its horsepower one way or the other, by the mere addition of exhaust gas, costing nothing, and adding nothing to the weight of the engine.

To appreciate the possibilities of the use of exhaust gas in this manner, let us suppose that we have a fuel of 0 toluene value. With such a fuel the highest compression ratio we can use if the engine is to be capable of running "wide open" at ground level, and with an economical setting, is only 4.85:1, corresponding to a limiting thermal efficiency of 32.7 per cent. By the addition of cooled exhaust gas a compression ratio of say 7:1 giving a limiting thermal efficiency of 38.6 per cent could be used and still permit of the engine being run wide open on the ground with perfect safety, and developing even at ground level very nearly the same power as the lower compression engine. As the machine ascended the quantity of exhaust gas would be reduced until at about 12,000 ft. it could be cut off altogether. It will be seen that, in this manner, not only can a high compression engine be made to operate safely on the ground with any fuel, but that the control of exhaust gas can be made to afford a very efficient altitude compensator. By way of comparison, tests were run with varying compressions and with a fuel of 0 toluene value in order to ascertain the relation between mean pressure, compression pressure, and compression ratio when detonation is prevented by throttling. The results obtained are shown in Fig. 4, and require no particular explanation. It is interesting to note, however, that detonation became apparent at very nearly the same compression pressure in all cases. By way of comparison it will be noted that with this fuel the throttled engine with 7:1 compression ratio can develop only 57 per cent of its full power on the ground while the exhaust controlled engine can develop 84 per cent.

Safety Fuels.—A good deal of interest has been shown lately in the question of employing fuels of high flashpoint to avoid fire risks. So far as the writer is aware, kerosene only has as yet been seriously considered. There are two possible methods of dealing with this fuel: (1) by vaporizing it and so using it in a normal type of engine; (2) by injecting it into the cylinder as a liquid, either during the suction stroke or at the end of compression. With regard to the first method, commercial kerosene consists almost entirely of heavy fractions of the paraffin series. These are all chain compounds, and their chemical stability decreases with increase in molecular weight. From the point of view of detonation, therefore, kerosene is one of the most troublesome fuels in existence. Further, in order to vaporize a reasonable proportion of it, it is necessary to raise its initial temperature to certainly not less than 140 deg. Fahr. This means a reduction in the weight of charge of at least 20 per cent as compared with gasoline, and a corresponding reduction in mean pressure. Further owing to its chemical instability on the one hand and the high compression temperature resulting from pre-heating, the limiting compression is reduced to about 4.2:1, corresponding to a limiting thermal efficiency of only 30.2 per cent and a limiting indicated mean pressure of only about 115 lb. per square inch, or say; 100 lb. per square inch brake pressure. Again, no means have yet been discovered of preventing the heavier fractions condensing on the cylinder walls and passing down into the crank-case, where they soon prove destructive to the bearings, etc. So serious has this trouble proved in the cast of stationary kerosene engines that so far the only kerosene engines of normal type which have given consistently satisfactory results over long periods are those in which the working parts are open and each bearing is lubricated individually. Although detonation can be kept in check and a comparatively high compression ratio employed with the help of the addition of exhaust gas, yet the low-power output, the condensation trouble, and the low efficiency are such serious drawbacks as, in the writer's opinion, to put kerosene out of court as a fuel for existing types of aero engines. The alternative method of injecting the fuel is not much more hopeful so long as it is applied to the existing type of engine. If the fuel is injected on the suction stroke one avoids the loss due to pre-heating, and can, therefore, use a higher compression and obtain considerably higher power, but the condensation trouble becomes more serious than ever, while the problem of measuring and pumping small quantities of fuel and maintaining correct proportions between the fuel and air at all loads and speeds is no easy one.

Lastly, if the fuel be admitted at the end of compression and ignited on entry by means of a hot plate or other igniter, the very formidable difficulty of so pulverizing and distributing the fuel that each particle can find at once the necessary air for complete combustion has got to be tackled; it is one which is very familiar to the author from bitter experience with Diesel and semi-Diesel engines. There is, however, another way of dealing with the high flashpoint fuel problem which, in the writer's opinion, is the most hopeful at the moment. Many natural kerosenes contain a considerable proportion of heavy aromatic hydrocarbons having the same characteristics as regards flashpoint as the kerosene of which they form part. These aromatics burn with a smoky flame, and are therefore very objectionable when the fuel is used as an illuminant. Recently steps have been taken to isolate and remove these heavy aromatics, and at the present time they are being removed at the rate of several thousand tons per month. Their use as a safety fuel for aircraft engines is worthy of careful consideration. Owing to their almost complete immunity from detonation they can be used with a very high compression ratio, even after preheating in a vaporizer. Experiments made with these aromatic extracts show that with an inlet temperature of 140 deg. Fahr. it is still possible to use a compression ratio as high as 6:1, and even 6.5:1, with the result that the efficiency is very high and the power output equal to or very nearly equal to that obtained with ordinary gasoline of low toluene value. Direct comparative tests carried out with kerosene and samples of these aromatic extracts gave the following results:—Kerosene, sp. gr. 0.812; I.M.E.P., 111.0; fuel pt. per 1 h.p. hour, 0.595; aromatic extracts, sp. gr. 0.884; I.M.E.P., 125.5; fuel pt. per 1 h.p. hour, 0.42. In both cases exactly the same vaporizer temperature was used, the only difference being in the compression ratio employed. The results obtained are, in the writer's opinion, sufficiently encouraging to justify further investigation. The difficulty of condensation still remains, but this appears to be less serious than with kerosene, since the freedom from any tendency to detonate permits of more pre-heating, while it is open to question whether the heavy aromatic condensate is as destructive to lubrication as the kerosene.

Influence of Mixture Strength.—Because of the losses to dissociation, change of specific heat and direct heat losses, the limiting efficiency obtainable under the best conceivable conditions is only about 70 per cent of the air cycle. Now each of these sources of loss is a direct function of the maximum temperature, which in turn is dependent upon the mixture strength. When the mixture is so proportioned that the whole of the available oxygen is just combined, the maximum temperature rises to approximately 4500 deg. Fahr., and the mixture strength is then approximately 47 ft.-lb. per cubic inch. As the mixture is weakened the maximum temperature is, of course, reduced, at first only very slightly, but so long as a homogeneous mixture is employed it is not possible to reduce the mixture to below about 40 ft.-lb. per cubic inch, without serious loss of efficiency due to incomplete combustion, owing to the limited range of burning of all volatile hydrocarbon fuels.

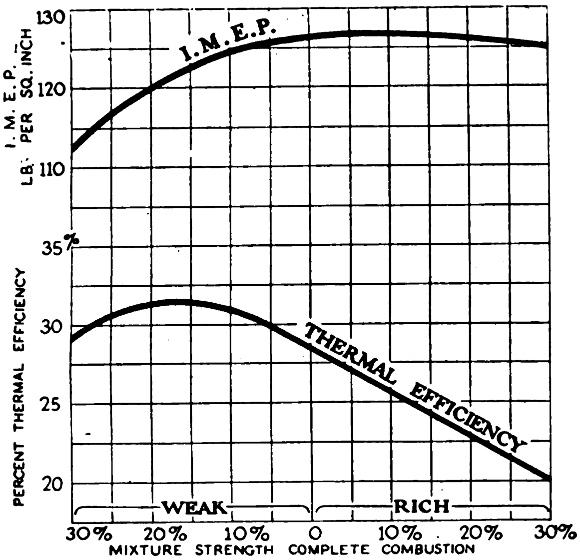

Fig. 5—Curves showing I. M. E. P. and thermal efficiency with varying mixture strength, compression ratio 6:1. Fuel, benzol

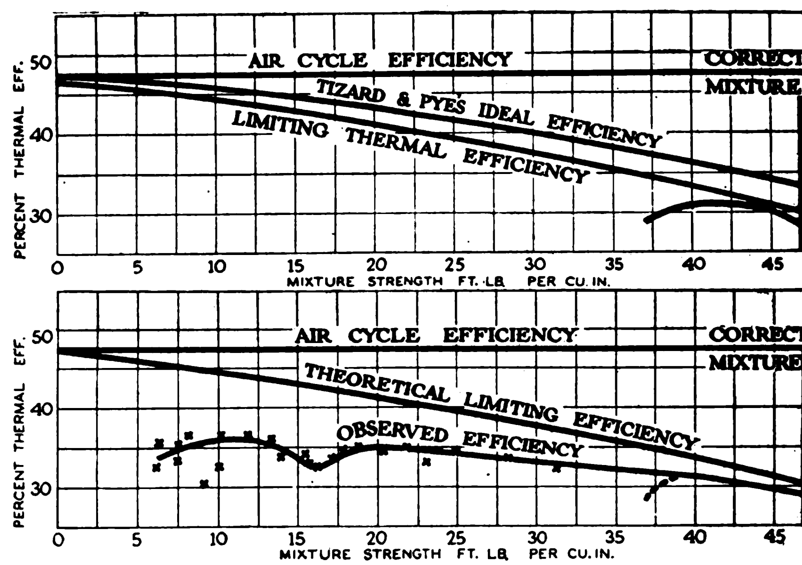

Fig. 6 (Upper)—Curves showing air standard efficiency, actual and theoretical, down to the point of no heat supply. Compression 5:1

Fig. 7 (Lower)—Curves showing efficiencies and mixture strength for bulb engine

The writer has carried out a very large number of tests on about 40 different fuels in order to ascertain the relation between mixture strength, power and economy. Except for insignificant variations, the characteristic efficiency and power obtained by gradually weakening the mixture is the same for all fuels and at all compressions, excepting alcohol, which on account of its greater latent heat and its large increase in specific volume gives increasing power as the mixture is enriched for a long period after the point of complete combustion has been passed.

The curve (Fig. 5) shows the relation between thermal efficiency and mixture strength expressed in terms of mean pressure. The example shown is taken with benzol at a compression ratio of 6:1 and, with but infinitesimal variations, it may be taken as applying to any fuel except alcohol. It will be observed that maximum efficiency is obtained when the mixture strength is such that the mean effective pressure is about 3 per cent below the maximum. Any further weakening of the mixture results merely in loss of efficiency due to incomplete combustion.

Now were it possible to control the power output by mixture strength alone, and still obtain complete combustion, it is clear that the maximum temperature would then be proportioned to the load and would diminish as the load is reduced. As the temperature diminished so also would the losses due to dissociation, change of specific heat, and direct heat loss diminish until at the point of no load and, therefore, of no heat supply, they would disappear entirely and the limiting efficiency would be virtually coincident with the air cycle. The accompanying curve (Fig. 6) shows how, under these conditions, the limiting thermal efficiency would vary with the load. In this diagram the horizontal line denotes the air-cycle efficiency, which, since it takes no account of heat losses, etc., is constant for all loads, the sloping line denotes the theoretical limiting efficiency over the range from no load to full load, the third line represents the limiting efficiency with minimum heat losses, and the fourth the actual test results obtained over the range of mixture strength available with a homogeneous charge. While it is not possible to weaken the mixture strength so long as the charge is homogeneous, it is possible to do so by means of stratification, that is to say, by supplying the cylinder with a relatively small charge of combustible mixture and admitting separately a large charge of air, keeping the two separate until after ignition. To do this it is necessary to reconcile two conflicting conditions—the two portions of the charge must be prevented from mixing till after ignition, and at the same time there must be sufficient turbulence in the combustible charge to insure rapid combustion. These two conditions are not irreconcilable, and the writer has succeeded experimentally on two engines in obtaining the whole range from dead light to full load by controlling the fuel alone. **Under these circumstances not only is the efficiency on reduced loads far higher than could be obtained by any other means, but the heat loss is so low that a water-cooled engine can be run at reduced loads for any length of time without cooling water.**

The accompanying curve (Fig. 7) shows the efficiency actually obtained in one experimental engine with a compression ratio of only 5:1. **It will be observed that it rises to no less than 37 per cent at about one-third full load corresponding to a fuel consumption of just under**

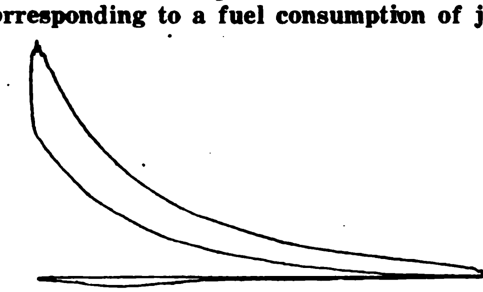

Fig. 8—Indicator card from experimental engine using excess air

0.36 pint of benzol per indicated horsepower-hour. It will be seen that the curve of efficiency actually obtained follows the theoretical curve with a reasonable degree of approximation. In Fig. 8 is shown a typical indicator diagram taken from one of the two engines with a Hopkinson optical indicator. **It should be noted that when working on this system distribution troubles disappear.** In any ordinary multi-cylinder engine it is necessary so to proportion the mixture that the weakest cylinder receives a charge of a certain minimum strength to insure regular running; this means that other cylinders are receiving a slightly richer charge than is absolutely

necessary and their efficiency is therefore reduced. On the other hand, when working with a stratified charge, the power output of each cylinder is dependent solely upon the quality of fuel admitted to it, so that any cylinder which receives a richer mixture than others will develop correspondingly more power, and the economy will always be at a maximum, that is assuming, of course, that the mixture strength is at all times below that required to consume the whole of the oxygen. Again, from the point of view of altitude compensation nothing could be simpler, for (so long as the oxygen in the cylinder is not all consumed) constant power can be maintained over any reasonable range of density by merely supplying a constant fuel feed, e.g., by gravity, or if a carbureter is used in its crudest form, the variation in power with altitude will correspond with the natural characteristic of the carbureter and will, therefore, vary as the square root of the density.

With a view to gaining further practical experience with this system, one of the two gas engines supplying power to the writer's laboratory was, about nine months ago, converted to run with stratified charge and control on the fuel alone. Since that date it has run continuously under violently fluctuating loads and has developed no trouble of any kind. It is running in parallel with another engine identical in every respect but working on the ordinary cycle. **In the case of the latter engine it is necessary to remove the cylinder head every two months for decarbonizing and grinding in the exhaust valve, while the cylinder of the engine working on the stratified charge has only been opened once, when it was found to be practically clean, while the exhaust valve appeared to keep almost as cool as the inlet valve in the other engine.** As regards governing and regularity of running there is nothing to choose between the two engines, each of which can develop a maximum of 24 brake horsepower at 750 r.p.m. Although the above experiments suggest that the system has been developed to a practical stage, the writer feels that this is hardly yet the case, and that considerably more research is required before it can be considered wholly satisfactory. In the writer's opinion **the potentialities of working with a stratified charge cannot be over-estimated. It opens up the possibility of obtaining far higher efficiencies than are obtainable by any other known means, and what is perhaps equally important, it reduces the temperature of the cycle and with it all the troubles due to high temperatures which directly or indirectly are the root cause of most mechanical failures.** Since the rate of heat flow to the cylinder walls varies roughly as the cube of temperature, and the power output practically directly as the temperature, **it follows that quite a small reduction in power will reduce the heat losses to an extent that must render air-cooling quite a simple problem.**

The possibilities of working with a short compression and long expansion stroke deserve careful consideration. In effect this can be accomplished by the simple expedient of closing the inlet valve late, so that compression does not start until well up the compression stroke; this method has both direct and indirect advantages. The direct advantages are that while the compression pressure is controlled by the nature of the fuel, the expansion ratio can be extended to any degree and very high efficiencies can be obtained, though, of course, at the expense of the power developed per unit of cylinder volume. For example, suppose that a fuel of 0 toluene value is used, then while the compression ratio is limited to 4.85:1 on the ground, the expansion ratio may be say 8:1. The limiting efficiency for 4.85:1 expansion is 32.7 per cent, and for 8:1, 40.6 per cent, the power output under these conditions will therefore be 4.85/8 or 60

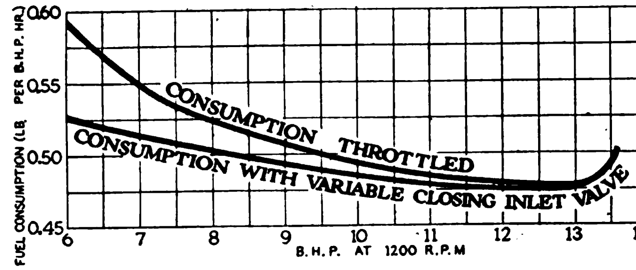

Fig. 9—Curves showing comparative fuel consumption when throttled and with late closing inlet valve

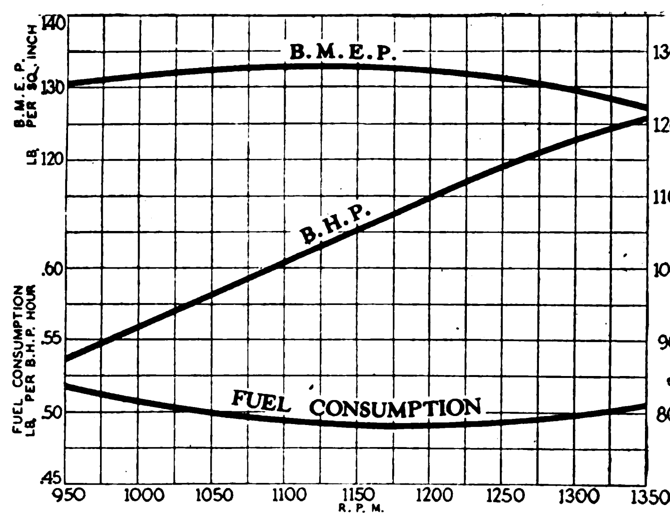

Fig. 10—Curve showing performance of 100 hp. single cylinder engine

per cent of that obtainable with an 8:1 compression, assuming that such a compression could be employed, or 73 per cent of that obtainable if both compression and expansion ratios were 4.85:1. By varying the time of closing of the inlet valve the compression could be increased as the machine ascended, until at about 15,000 ft. the full compression could be used and full power developed. Thus the indicated thermal efficiency could be maintained at a maximum and the power nearly constant over this range of altitude.

The indirect advantages are:

(1) That with such a valve setting the engine has a rising torque curve which is a desirable characteristic.

(2) In the event of one cylinder dropping out and the speed falling in consequence, the compression in the remaining cylinders is reduced, and the shocks due to the irregular turning moment are also reduced. When controlled by throttling, the reverse is the case; if one cylinder drops out the others, owing to the drop in speed, take in a heavier charge, resulting in severe shocks and increased liability to detonation and pre-ignition.

(3) When working with a late-closing inlet valve the whole charge enters the cylinder and a portion is rejected. The rejected portion, which returns to the manifold, has picked up a considerable amount of heat from the inlet valves, cylinder walls and residual exhaust gases, some of which heat it imparts to the inlet manifold with the result that, as the load is reduced, so is the temperature of the manifold increased, which is a desirable characteristic.

Some years ago the writer carried out a series of experiments with a variable inlet cam fitted to a small engine having an expansion ratio of 5.95:1. A number of very careful comparative power and consumption tests were made, the power output of the engine being controlled in the one case by varying the time of closing of the inlet valve, and in the other by using a normal valve

setting and throttling the charge. The results obtained in these experiments are shown in Fig. 9, from which it will be observed that the gain in efficiency in the former case, though perhaps not so large, is none the less quite appreciable. It should be noted that in these experiments the same expansion ratio was used in both cases, so that the advantage due to prolonged expansion was not obtained, and the gain in economy recorded is that due to indirect advantages alone.

Designing for Best Performance at Given Density

In aircraft engines when one is working over a large range of atmospheric density the question always arises —at what density the engine shall be designed to give its best performance or at least to develop its full power. Until comparatively recently all engines were so designed that they could develop their full power at ground level, without pre-ignition, without overheating, and without overstressing the parts. During the war, however, it became evident that this was unnecessary and undesirable, and manufacturers were urged to design their engines on the assumption that they would not be opened wide below 10,000 ft. So far as the writer is aware, no manufacturers actually produced such an engine. It is, however, interesting to consider what might be done in this direction. We will begin with the assumption that modern aviation spirit has a toluene value of 10, which is about the average value of American aviation spirit. At 10,000 ft. the air density is 0.72, and at this density a compression ratio of 7.0:1 could be used with such a fuel, giving a theoretical limiting thermal efficiency of 38.8 per cent and a theoretical limiting mean pressure of approximately 165 lb. per square inch reckoned at ground level or 119 lb. per square inch at 10,000 ft. Under these conditions let us now consider what power the engine could develop at ground level, keeping just free from detonation. If controlled by throttling the maximum indicated mean pressure would be approximately 95 lb. per square inch. If controlled by varying the time of closing of the inlet valve it would be considerably higher, because for various reasons the efficiency obtainable under these conditions is greater and would be very nearly in the ratio of $5.25:7.0 \times 165$ (5.25 being the limiting ground level compression ratio for a fuel of toluene value 10) or say about 122 lb. per square inch. If controlled by the addition of cooled exhaust gas the mean effective pressure, as shown previously, would be very nearly equal to the full available M. E. P. with a compression ratio of 5.25:1 or 140 lb. per square inch.

In all cases let us assume that the mechanical losses of the engine are equivalent to an M. E. P. of 15 lb. (a fair average figure). Then the theoretical limiting brake mean pressure in the three cases would be:

(1) 80 lb. per square inch.
(2) 107 lb. per square inch.
(3) 115 lb. per square inch, while at 10,000 ft. the brake M. E. P. will be 104 lb. in all cases.

Use of Exhaust Gas to Enable Higher Compression

In all three cases the explosion pressure would be substantially the same, and little or no higher than at 10,000 ft.—that is about 450 lb. to 500 lb. per square inch. In the latter case it will probably be actually lower, because the principal effect of the exhaust gas is to slow down the rate of burning and so round off the peak of the diagram. Assuming that the propeller torque varies as the square of the speed and directly as the density, then, if the engine is designed to run wide open at 10,000 ft. at 1500 r.p.m., its maximum speeds at ground level will be approximately 1100 r.p.m., 1270 r.p.m. and 1320 r.p.m., respectively. In the former case such an engine would probably fail to leave the ground.

From these considerations it seems clear that the principle of designing a very high compression engine for use at high altitudes and throttling it on or near the ground is not the right one Of the three methods considered, the use of exhaust products appears to be the most hopeful as a means of permitting a very high compression engine to operate satisfactory at low altitudes, and still have sufficient power to get rapidly off the ground. The alternative method of dealing with the problem of varying atmospheric pressure is to maintain artificially ground level density in the cylinder at high altitudes by supercharging. From the point of view of engine weight there can be no doubt that this method scores heavily, for, although the strength and weight of many of the parts may be proportional to the density in the cylinder, there still remains a very considerable number whose weight is altogether independent of the pressure in the cylinder, so that the weight of the engine, as a whole, can only vary as the density plus a very large constant.

There are at least two possible ways of dealing with the supercharging problem, one by merely forcing more fuel and air into the cylinder by means of a pump or blower and the other by employing a supercharge of pure air in a stratified form. Some four years ago the writer carried out a very extensive series of tests on this latter system, and obtained most encouraging results on two experimental engines, but had to break off these experiments and concentrate all his attention on engines for tanks. The results obtained were, however, so encouraging that further tests should be made. Apart from the obvious increase in power at high altitudes this system of supercharging provides a perfect and automatic compensation of mixture strength for altitude, and gives a considerable increase in economy, the consumption falling from 0.49 lb. per brake horsepower-hour when running normally to 0.455 lb. when supercharging.

Limiting Size of Cylinder.—Designers of aircraft engines have, in the writer's opinion, shown quite unnecessary timidity in regard to the power output obtainable from individual cylinders. So far as the writer is aware no one has yet had the courage to construct an aero engine with cylinders developing more than 50 hp. each. Some two and a half years ago, as a result of experience with large cylinders on tank engines, the writer was requested by the Air Board to design an engine for aircraft to develop 100 hp. per cylinder. A complete design was prepared, and after much delay a single cylinder unit was built at Farnborough having a bore of 204 mm. and a stroke of 280 mm. This unit has been running on and off for over a year. Apart from a failure of the valve gear at first which has never been quite explained, it has given very little trouble and no trouble at all which can be attributed to its large size. In view of the fact that its compression ratio is only 4.84:1, the results obtained are rather extraordinary and constitute, the writer believes, quite a record for so low a compression. From the accompanying curves, Fig. 10, it will be observed that this single-cylinder unit develops 120 brake horsepower when running at 1350 r.p.m. with a consumption of only 0.493 lb. per brake horsepower-hour at its normal speed of 1250 r.p.m., corresponding to an indicated thermal efficiency of 31.2 per cent, or within 4 per cent of the limiting value for this compression and an indicated mean pressure of 150 lb. per square inch. These results will, the writer hopes, help to dispose of the myth that very large cylinders can only operate with relatively low mean pressures and at a low efficiency.

Time Study Work Requires High Grade Men

A prominent industrial engineer points out that the time study man is the connecting link between the management and the working force; that he reflects the policies and attitude of the employer. He believes that the time study man is important in the adjustment of industrial relationships.

By William Baum

LOOKING into the future of shop and factory methods, William Baum, industrial engineer for a large textile concern in Milwaukee, and consultant for a number of Milwaukee industries, says that co-operation in time studies and organization methods between employer and employee, even to the extent of sharing the expense, will be found necessary. Both sides must see that time study is highly ethical, and is for the purpose of determining the time required to perform an operation which will be fair and just to employee and employer.

Mr. Baum's views, as expressed recently before the Society of Industrial Engineers of America hinge on the importance of training of time study men at this time in the light of future conditions in the labor and production situation, and are in substance as follows:

"The importance of standardization and scientific wage systems based upon time and motion studies is well understood by progressive industrial managers, who begin to reap the great benefit derived from the introduction of scientific management systems. Wherever such systems have been installed by responsible and competent engineers they have resulted in greater production, lower unit costs and higher wages.

"The men charged with the important task of making time studies must be qualified to make an analysis of manual, mental or machine processes into the smallest elements; to eliminate waste of time, energy, tools and health; to establish proper allowances for fatigue and unavoidable delays, and to determine the one best way of operation and process. It can be readily seen that the skillful handling of the stop watch is not the only factor which enters into the training of time study men.

"Their training should be as broad as possible. In many years of training of time study men I have found that the graduate mechanical, electrical or chemical engineer makes the best time study man, especially if he has had some shop practice. The college man has the advantage that his mind has been trained to take accurate observations in the physical and chemical laboratory. It is this foundation of thinking and working scientifically which enables him to learn and master the intricacies of industrial time study work in a comparatively short time.

If engineering students in our colleges could be given an opportunity to attend courses and laboratories on time studies, using proper text books, they would be amply prepared to take up the work in the industries. Herrick's Class Book would be proper.

"As the matter now stands, most successful industrial engineers train their own forces, not according to hard and fast rules, but by letting them 'go through the mill.'

"The training of time study men is not only a matter of teaching the technique of the art. In practice the time study man is the connecting link between the management and the working force. He reflects voluntarily or involuntarily the policies and the attitude of the employer which reacts in one or the other way upon the man in the shop. If the time study man has a broad conception of his position, he will have the desire to be a servant to both his employer and the employee. After all, the object of taking time study is a highly ethical one—to determine the time which is required to perform an operation and which is considered fair and just to employees and employer.

"Most labor disputes hinge on wage questions and can be reduced to a minimum only if the basis for setting the rates is correct, represents the truth and is indorsed by the one who works and the one for whom the work is done. In fact, the time may not be far off when the industrial engineer and his time study assistants will be the true servants to both management and working force, and as such be paid in equal proportions by both parties. The garment workers in Cleveland have already set an example.

"There is no group of workers or a self-respecting union which could afford to reject or resent time studies if such work is done in absolute fairness to the men as well as to the company. Naturally, when the time-study engineer is the personal emissary of the manager, suspicion arises among the workers, who see in the time-study man only a driver, an intruding observer of their work. Let the time-study man be the unbiased friend to both workers and management, employed and paid for by both, and the results will be most satisfactory from a production view as well as industrial relationship.

"The success or failure of any scientific wage system will depend not only upon the characteristics of any system to fit existing conditions but also upon the skill and particularly upon the personality of the time-study man. In his mind must be instilled the highest principles of professional ethics, integrity and honesty. If he is earnestly interested in the welfare of the workers, understands human nature and is willing to stand for the truth under all circumstances, he will secure the trust and confidence of all men and women who see in him their friend and adviser."

THE automobile carries, at some stage, practically all of the products of the steel mills and tons of freight carried by the railroads.

Edge Act Corporation Proposes to Finance Foreign Trade

The attention of manufacturers interested in export development is directed to a statement of the proposed Export Trade Financing Corporation, which is inviting purchase of stock. This banking institution proposes to finance America's trade abroad.

AN interesting and important development in the export field is that of the opening of the stock subscription books of the Foreign Trade Financing Corp. The proposal to organize this corporation is based on the Edge Act, an amendment to the Federal Reserve Act. This amendment is practically authority for American banking interests to extend their financing to foreign countries when necessary to aid American trade. The Edge Act is complemental to the Webb Act. Under the Webb Act several manufacturers could form a sales company and this company could act as sales agent abroad for lines so closely related that they would be considered competitive in this country.

The Edge Act does not authorize selling companies but applies similarly to the banking feature. This corporation will not sell, nor will it supplant abroad the branches of American banks. It will rather serve as a Federal Reserve Bank for the foreign deals of the banks and selling companies. It will aid rather than supplant the branch banks.

This company was tentatively formed at the annual meeting of the American Bankers' Association at Washington last October. The next step was taken at Chicago Dec. 10 and 11, last year, when the heads of many national trade societies met at the call of the president of the American Bankers' Association. At that meeting it was decided to invite W. P. G. Harding, Governor of the Federal Reserve Bank, to become head of this corporation. The importance of this proposed organization can be judged by the fact that Mr. Harding has accepted this invitation.

The Foreign Trade Financing Corp. proposes to raise $100,000,000 by selling stock. With this stock sale return as a beginning, deals will be extended by the sale of debentures, based upon loans made to finance foreign trade. The sale of these debentures will supply capital, it is said, to the extent of $1,100,000,000 total, if that amount is required.

It is announced that the capital of the corporation will be used to aid the industries that subscribe for it. In other words, if the automotive industry subscribes heavily to this stock, it will be used for automotive loans in proportion, if it is needed.

This corporation is not merely a friendly aid society. It will make a profit on its deals. Banks, manufacturers and individuals are invited to subscribe for stock. Its object, however, is to be helpful in distributing the overproduction of raw materials in America to countries where the raw material is required, and to finance the manufacture of this raw material into finished products. The Committee on Organization of the Corporation includes many bankers and leaders in national trade organizations. J. G. Culbertson, John J. Raskob and Roy D. Chapin of the automotive industries are members. Communications regarding the purchase of stock should be addressed to Committee on Organization, 66 Broadway, New York.

British Body Work

THE Wellington (New Zealand) correspondent of the London *Times*, after noting a large increase of value in the motor imports of the Colony during the first eight months of 1920—the value of this increase being about $5,700,000—mentions that a belated delivery of cars was then taking place, and that *the percentage of British and European cars and cycles is very small.* He adds the *important remark that the American cars are of the class which the market requires*, and that some recent *arrivals of British cars had been a disappointment as regards the bodywork.* Apparently he means this criticism to apply to British cars of the type intended to compete with the American models which have the largest sale.

He eulogizes British trucks, which he thinks cannot be ousted by rivals, and notes that there is a growing market for trucks, especially among farmers, dairymen, etc.

Merchandising Abroad

DURING recent months many American business men have visited Europe and upon their return each one has told of his impressions. Very often these impressions have had to do largely with the political and international aspects of the situation "over there," and, while interesting to a certain extent, have not given much food for thought in connection with the immediate practical activities of other American manufacturers.

Like others who have gone abroad since the armistice was signed, E. V. Hennecke, of the Motometer Co., Inc., who recently returned from several months in England and France, was impressed with the economic significance of certain aspects of the political situation. He gained also, however, some interesting and definite impressions as regards business and merchandising methods, which have a rather direct bearing upon some of the foreign trade problems now confronting other automotive manufacturers.

One factor not sufficiently recognized usually by American manufacturers in attempting to merchandise their product in England, is the difference between our system of distribution and the system commonly used in Britain. In the case of automobile accessories, for instance, it is common over here to market through a jobber and then through a dealer. In England, however, the manufacturer usually sells direct to the dealers or the jobber sells directly to the consumer. In other words, one distribution unit is eliminated. This is made pos-

sible chiefly by the smaller area over which distribution takes place and partly by long established custom.

Merchandising organization, moreover, has not been carried to so great a degree of refinement as in this country, although British and French manufacturers are rapidly improving in this respect. Many of them are molding their advertising catalogues and their merchandising efforts along the lines generally used in this country, and they may be expected to equal us in this respect before many years have passed.

On the other hand, Hennecke found, merchandising cannot be conducted on the rapid, aggressive manner that is common in America. Things just don't move that fast in England and French business. Many American manufacturers have expended a great deal of useless money in trying to merchandise in these countries exactly as they have successfully done at home. They have expected too rapid results, and as a result have often obtained few results at all.

The American manufacturer needs a very thorough knowledge of the customs and methods used in England or France if he is to attempt to conduct his own merchandising campaign. In many cases he will do better to get a native Englishman to conduct his entire selling campaign for him—making certain, of course, that he has chosen a competent and efficient representative. This is often good policy for several other reasons.

In England, for instance, Hennecke found that the trade-mark "Made in U. S. A." is almost a certain bar to the sale of a product at the present time. This is true, he says, even in regard to consumer sales. The unfavorable rate of exchange is, of course, one reason for this condition, but there is also a strong prejudice against American goods because America bids fair to take away from the British their former economic domination. It is surprising to note the pride taken by the average Englishman in the trade superiority of his country.

When the American product is manufactured in England, however, much of this prejudice is dissipated, since the Englishman then feels more favorable toward it since English labor is being used in making it and taxes on the profits are paid to help support the English government.

In France, however, the situation appears to be different. There is a great love for America and the trade mark "Made in U. S. A." is a help to the sale of goods despite the extremely unfavorable rate of exchange.

There are often local peculiarities which have a very definite bearing upon the sale of an American article in foreign countries, and the American manufacturer who attempts to merchandise without a thorough understanding of local conditions is very likely to fail in his efforts without ever being able to understand the real causes for his lack of success. Hennecke cited an example of this in connection with the product of his own company, the motometer.

He found that in England there are two very powerful automobile clubs, the R. A. C. and the A. A. A., both of which use a special insignia placed on the top of the radiator cap. This insignia is not only ornamental, but entitles members to certain desirable privileges while touring, and is considered by members of these societies as a very essential part of their motor equipment. Obviously, this fact creates an increased sales resistance for the motometer and constitutes one of the factors which must be overcome in merchandising.

This instance is cited simply as an example of the kind of local condition which is likely to make merchandising difficult for any specific product in a particular case. It emphasizes the need for a close analysis of markets before the investment of capital in selling effort.

Speaking of general conditions in the automotive industry in England and France, Hennecke stated that he found things very dull in practically every instance. Many of the English plants were entirely shut down, while those in operation were proceeding on greatly curtailed schedule. Optimism prevailed throughout the trade, however, and an early return to normal is expected.

The accessories business in these countries is not developed to nearly so high a degree as in America, and there is an excellent opportunity for American manufacturers in this line of automotive equipment.

Hennecke got one very vivid impression during his stay in France. It was the apparent determination of the French people to get to work and repair the damage done by the war. Everyone there, he said, seemed to be filled with a spirit of industry and there seemed to be a strong individual, as well as general, effort to get to work and stay at work. There appeared to be less industrial unrest in France than in England.

A Britisher's Opinion

AMERICAN engineers might well be interested in this comment by A. J. Hancock, works manager of the Vauxhall Motors, a well-known British plant. This comment was made after a visit to America, which included a number of factories. The comment follows:

"As a result of my visit I am not despondent over England's future," said Mr. Hancock. "What I have seen simply means that the English must work just a shade harder in industry, and that people of our working class need to lend themselves to the arts of quantity production in a manner they are now disinclined to adopt.

"It is a revelation to see able-bodied workmen in America doing repetition work so fast and with such apparent interest. They do it much faster than the English worker who uses the same appliances. We must change this in England in order to hold our place against American competition in the world markets. American enterprise rides to a big gain or a big fall. American capitalists take bigger risks. For instance, the heads of a firm will say: 'Let us lay down a million more feet of floor space' as readily as English business men would say: 'Let us lay down a thousand feet.' I am of opinion that America has lost the sense of the ideal in its successful search for quantity production.

"The better classes of American motor cars lack the simplicity of design and the taste in finish that characterize the English product. If we were to take over the manufacture of some of the best-known trans-Atlantic motor cars we would simplify the design and do away with many parts. For instance, Vauxhall cars, at the present rate of exchange, are priced in the neighborhood of $4,000. Compared with American cars in this price category they will do all United States products will do, at less expense, with less complication; and they are a perfectly turned out job. Many American cars of the better class are too heavy, and are extravagant in the use of fuel.

"I am perplexed over the fuel situation. In our country the high cost of gasoline compels economy. Motor design of the future must turn toward more economical motors. If every motor car—every Ford car, even—was to have its fuel consumption reduced 10 per cent the price of gasoline would drop 50 per cent. Automotive engineers will solve the problem. A fuel consumption of between 30 and 40 miles to the gallon is not improbable for the middle size touring car of the future."

Transmission Brakes

Editor AUTOMOTIVE INDUSTRIES: Viewed from the standpoint of those who live or drive in mountainous sections, the transmission brake should be the emergency brake. If *both* brakes operated on the shaft, with the service brake arranged as the less powerful one, it would be better than the two wheel brakes on many present cars and fully as safe as the latter.

The transmission brake distributes the retarding effort more equally than is possible with wheel brakes under varying load—and loads are rarely constant. But where there are long descents, the heat from constant application of the shaft service brakes frequently sets fire to the floor boards. Hence, for driving in hilly country the transmission brake is better when actuated by the hand lever.

There is no good reason why wheel brakes could not be of as high a grade of design as other parts of a car or why the external brakes could not be partially enclosed at little expense. The transmission brake has undoubtedly received more attention from its position and general environment, being a part of the unit power plant in many cases and directly related to other members which are better made and run truer than wheel parts.

So long as we tolerate that mechanical misfit—the Hotchkiss drive—so long shall we have shaft brakes. Of course, there are and have been Hotchkiss drive cars of an otherwise high grade that were fitted with wheel brakes only. The writer has yet to see one of these cars that you could be sure of holding if you had to stop when ascending a steep hill; if the brakes were adjusted for good service in a forward direction, you could push them to the floor board without stopping the car from rolling backwards. The same is true if the adjustment is made with a full load and the brakes are put to the test with but a fraction of this. This becomes a serious matter where there are frequent or long hills with grades of seven per cent or more—particularly if the traffic is heavy. Under such circumstances, the shaft brake is one's only salvation. DONALD A. HAMPSON.

Urging Wood Conservation

Immediately on reading the editorial on "Wood Conservation" in the issue of AUTOMOTIVE INDUSTRIES of Jan. 6 Cornelius T. Myers addressed the following letter to the members of congress to whom he feels entitled to express his views. We commend this course of action to other engineers and to manufacturers.

Hon. Earnest R. Ackerman,

I wish to write you in behalf of an appropriation of $400,000 which the Forest Products Laboratory at Madison is seeking in order to carry on its work the coming year.

I am personally acquainted with some of the work which has been done and some of the proposed program, and can say that it is not only theoretically constructive, but has been of great practical value to the wood working industry.

I appreciate and am in accord with the efforts of Congress to decrease governmental expenses to the minimum for the next few years, but would greatly deplore any economy with respect to so important a function as is being performed by the Forest Products Laboratory, which is, as you know, a branch of the Forest Service of the Department of Agriculture.

The value of the products of the wood working and using industries aggregates about ten billion dollars annually and these industries employ as many men as any other single industry in this country. It is conservatively estimated that the commercial application of the research work already done by the Forest Products Laboratory is saving the country thirty million dollars annually. To do other than appropriate money to continue so vital a work would be equivalent to letting your furnace fire go out in order to reduce the coal bill.

I can speak personally for the work of the Forest Products Laboratory and its very capable staff, and trust that you will give your personal attention to this item, both in committee and on the floor of Congress.

Rahway, N. J. CORNELIUS T. MYERS.

Action on Patent Bills Urgent

Editor AUTOMOTIVE INDUSTRIES:

For more than a generation there has been a constant petitioning of Congress to enact a law that would permit the Patent Office to use the money earned by it to promote the interests of patents. The patrons of the patent office are entitled to this service, as they pay for it. The refusal to permit this has caused to be returned to the United States Government more than $8,000,000 as profit. The men of long experience who worked so hard to make the Patent Office a success are gone—starved out. Men who can pass the required examinations will not take the places open at the salaries attached. The work is increasing 20 per cent a year since the war and the ablest men in the Patent Office are leaving it at the rate of 2 per cent a month. Our Patent Office is a wreck!

Erroneous and invalid patents are rushed through in an attempt to keep up with the work. These later clog the courts and cost the people much money. Assignments are a year behind the record clerks. One hundred and twenty thousand patents await action! Buyers of patents cannot ascertain titles. Copies of patents cannot be obtained because the records are lost or out of print.

And all because Congress does not authorize the money to hire enough men and pay enough to get them.

For a year the Nolan bill, H.R. 11,984, has been dragging along. Another 25 per cent of the best men have gone while it dragged. It has passed both Houses of Congress with some amendments and now has been passed by the Conference Committee and reported back to both Houses. A vote is expected in the House during the closing days of Congress. Every manufacturer, engineer and production man should urge its passage. Failure to pass this bill will lose another year and cost untold millions that the new business lodged in the Patent Office should and can bring. This is important to you. CHAS. E. DURYEA.

Since this letter was written the Nolan Bill has been passed by the House of Representatives, but has not yet been brought up by the Senate.

Mutual Benefit Should Be Major Thought in Dealer Contract

What is written here is not startling in any degree. There is not anything new in the faultfinding with the manufacturer-dealer contract in the automotive industry. It is merely a part of the growing pains. Next—what is the importance of the dealer in the trade?

By Clyde Jennings

THE recent announcement that a committee of the National Automobile Chamber of Commerce will meet with a committee of the National Automobile Dealers Association and discuss the relations of dealer and manufacturer is certainly reassuring. It is not to be supposed that this committee will draw a model contract and that instantly the present defects will be remedied by all manufacturers and distributors adopting a standard of dealing.

This will not be the result, nor can it be the result. The members of the two committees will not have the power to bind all of their members to a certain contract, nor would this be desirable. These committeemen, however, can have a considerable power for good. The contract which is the connecting link between the dealer and his source of supply of merchandise has been the subject of much criticism and of, perhaps, more misunderstanding. Both dealers and manufacturers' salesmanagers are human and their relations have been and will be subject to the misunderstandings that constantly arise in human organizations. It will be within the power of the men serving on this committee to point out some of the injustice suffered by their fellows and then carry the other side's story back to their membership. Such a move will undoubtedly serve a good end. Usually the terms of a contract become a subject of a dispute after both parties are angry and in no fit humor for proper consideration of a business proposition.

It is not the intention of this article to assert that all contracts are bad, nor that all are good. Indeed, the existing contracts appear to be on both sides of the fence. It is, perhaps, more important to regulate the spirit that carries out the contract than to regulate the contract itself. In this phase of the situation, the joint committee undoubtedly can have a very marked influence for a better understanding. The representatives of the two great national bodies should have the nerve to speak out to their fellow membership if their conferences develop marked evils.

This article is not going to present for your consideration a model contract. We do not believe there is such a thing, nor that any one contract will serve the needs of all manufacturers. Rather it is hoped to offer some remarks on contracts in general. These will apply to all contracts, just as they will to manufacturer-dealer contracts. Before attempting to write this article, I had an audience with a man who has been dealing with contracts in a large way for a number of years. He is not a lawyer, in fact does not pretend to know anything of law terms or of the technical effect of contracts. He says that these things are detail, in which he has no interest. He cares not so much for the exact wording of a contract as for the spirit of the contract. After leaving this man I held in mind a number of contract epigrams, and perhaps his views can best be expressed in this form. So here are some of his remarks.

A contract must be good to both parties. It must be fair.

A perfectly written contract is illegal if it is unjust and will be abrogated when brought into court.

Our contracts do not work so much on law as on justice and the man who brings a contract into court to enforce its terms must come with clean hands.

A contract to live must take into consideration a proper profit for both parties and must be so carried out regardless of the letter of the contract.

Business is not selfish; it is co-operative. No business can thrive on the losses of those connected with that business.

Honesty is the best policy. That saying has lived too long to be doubted. It is based on policy, or practice, and not on a moral foundation. Honesty is not and cannot be the mere living in keeping with a writing, but honesty must take into consideration the surroundings.

Of course this man had something more to say out of the wisdom that he has gathered in his long years in big business. It has been a part of his experience to take over several businesses that were in rather bad position. He has found it necessary, under these circumstances, to cancel many contracts. His belief in the native honesty of the average man has been greatly strengthened by these experiences. He did not notify the holders of these contracts of the cancellation, but he called them in to discuss the contract. He pointed out wherein these contracts were selfish, how they put an impossible handicap on the business and other things that we all know creep into contracts. Invariably he has found the man willing, in the end, to cancel his own contract. Often it required time for the man to think it over. Usually the holder of a selfish contract stiffened with opposition when the suggestion was made, and then realized his unfair position. He also realized that the success of the business was more important, even as regards himself, than his individual prosperity for a short period.

Let it be said here that the writer holds no brief for the manufacturer or the dealer in this contract discussion. It is quite well established that the dealer has suffered in many instances. Also it is established be-

yond question that the manufacturer has been the victim of the sharp practice dealer. The fault is not on one side. There are manufacturers who have not had a serious disagreement with a dealer in 15 years of merchandising. The dealers who have quit this service have left with good feeling. There are dealers who have sold for the same factory for 20 years and who assert that the factory management is entirely fair and reasonable; while other dealers have quit this same factory in a rage and later spread bad reports about the dealer relationships.

Recently a now prosperous New England dealer told of 19 years of service in the sale of a single car. Thrice during that period the ownership of the sales agency changed. Once because the dealer thought he did not get a square deal. Another time because the factory was not satisfied. The third time was when this employee bought into the sales agency, which he now controls. He says that during this period he has held steadfastly to the opinion that the factory sales department was entirely just in intent, and it was only necessary to properly present any particular incident to get justice. At the same time it has been the writer's experience to hear factory men speak of dealers as "foolish children" and in worse sounding terms. These are merely suggestions to indicate that no one rule will cure all ills.

Now for a moment we will return to the man of big business and his epigrams. Consider the first:

A contract must be good to both parties. It must be fair.

A recent communication tells of a factory making a contract that never had a chance. The factory was oversold at the time the contract was made. No effort was under way to increase production. This man required the profits on 100 cars a season to justify his establishment. He was promised 400. He received less than 50. Was that contract "good for both parties?" Turn it around. Is it "good for both parties" if a man enters into a contract to sell 100 cars a season, then buys one himself, sells one each to half a dozen relatives and then lays down on his job? Manufacturers will tell you of experiences of this kind.

New circumstances always will arise that are foreign to any clauses in the contract. No one ever imagined that in the winter of 1919 there would be hundreds of cars stored in the manufacturing district that could not be delivered before the buying wave exhausted itself. Some manufacturers realized the importance of this position when it developed, and, although it was foreign to the contract, assisted dealers in financing these cars. Some manufacturers did not. We ask you: Was it fair to hold the dealer to the letter of a contract when entirely unexpected circumstances arose?

Another of the epigrams:

A perfectly written contract is illegal if it is unjust and will be abrogated when brought into court.

The man of business illustrated this point in this way. During the war scarcity of raw materials he was forced by a very large company to sign a contract for $2,000,000 worth of material necessary to his business in order to obtain delivery. No price was named. The seller was to make the price at the time of delivery. "This was unfair," said my informant, "but I signed under duress. At once we began to lay plans for our own source of raw material. We are now in a safe position. When the market began to fall I cancelled this contract, because it was 'unfair.' I was willing to go into court. But the other party to this contract knew that it was unfair and was entirely unwilling to carry it into court, although the document probably was a model from a legal point of view."

Our courts do not work so much on law as on justice, and the man who brings a contract into court to enforce its terms must come with clean hands.

We hear much of law decisions that are based solely on the technicalities of the law. But the very fact that we hear so much of these few cases is an argument that court procedure—in the main—is based on justice. There are thousands of court decisions handed down daily. We hear little of the 999, but we do hear of the 1000th, which is the exception. Routine is not news. We would not read a newspaper that told only of the routine of life of the day laborer, or the busy, singing housewife in her house dress. We want to read of the man who is arrested, of the woman in gay clothing. Law decisions are no exception in news.

A contract to live must take into consideration a proper profit for both parties and must be so carried out regardless of the letter of the contract.

Comment on this would appear to be superfluous. Dealer franchises must always be based on production. The size of the town, the dealer expense, the opposition and other things must enter into the composition of a contract.

What good can it do a factory to have a large dealer list if the men whose names are on this list are standing in the financial soup line of their respective towns? The local customer judges the company by its dealer representation, not by the factory that he never saw.

Business is not selfish; it is co-operative.

The comment here is the same as just offered. The dealer who is not making money is not an asset to a factory. If it is the factory's fault, extra means must be taken to keep him satisfied. If it is the dealer's fault, eliminate him. Remember Roosevelt's utterance: "Speak softly, but carry a big stick." But if the contract is badly made, the factory cannot make a big stick out of it.

Honesty is the best policy.

All of us have seen so many organizations fail which were built on trickery and false pretense that we always wonder why men continue to "put it over."

A contract is necessary as a business memorandum. It should be just that. It should be a business agreement which can be shown to the banker to enable the dealer to obtain proper loans. His tenure as a dealer should be sensibly defined. If there is a penalty clause for one party, there should be a penalty clause for the other. It must be a mutual agreement to guide certain transactions, which gives to both parties an opportunity to be honest and prosperous. Then there should be the proper spirit behind it.

AN interesting motion picture, tracing the development of the gasoline engine and means of transportation, has been produced by the Cole Motor Co. The film has been named "The Porcelain Lamp" and had its premier showing at the Strand Theater during Show Week in New York.

The film pictures in dramatic manner the discovery of gasoline, the various modes of transportation from the time man had only his legs as a means of conveyance, the stages of development of the gasoline engine, and the development of the modern automobile. An interesting story is woven about that part of the picture which concerns the discovery of gasoline, and in the story a porcelain lamp plays an important part.

Workmen Feel Just Like the Rest of Us As Regards Wage Cuts

It is not surprising that the worker is putting up a fight against wage reductions. The history of the long division between labor and capital bears strongly on the matter, as does the amount and type of information available to the average worker. No man receives a cut in his earnings without raising some kick about it and determining to replace it.

By Harry Tipper

A LETTER which has been received this week affords us an opportunity to deal again with a matter that has formed the subject of several of these articles. This letter states:

> "The fact that labor is walking out immediately when they think they have the manufacturer in their power because of returning business is certainly striking a blow at any spirit of co-operation that might have been engendered in the heart of the manufacturers by the fact that they were compelled against their wishes to cut their wages. Without any bias and looking at the matter in a calm, unprejudiced way, manufacturers certainly made every effort to maintain wages. These were cut only as a last resort and the workmen certainly ought to know it. The fact that this is not appreciated by labor generally, as shown by the current strikes, in spite of the fact that thousands of people are out of employment, has greatly disappointed the employers and manufacturers here."

This statement indicates the lack of appreciation by the manufacturers as to the consequences of the long division of capital and labor, as these statements are ordinarily used. It was pointed out in these articles some time ago that the workers are not inclined to be any fairer in their approach to the labor question than the employers. In fact, with their ignorance of many of the factors entering into the situation, the kind of information they have and their desire for larger comfort they can be expected to retain any advantage they have gained as long as possible and combat any reduction in that advantage.

We have pointed out in these articles from time to time that the removal of suspicion of long standing is not to be accomplished in a few months or a few days, and that the difficulties in the way of agreement between employers and employees cannot be wiped out by a few efforts and a gesture or two.

The manufacturer is very apt to assume—because he knows his prices are being reduced at a more rapid pace than his costs—the worker should be equally well informed and accept the situation with as much resignation. The worker, however, is not equally well informed, what opinion he has does not agree with the manufacturer's information at all. A significant example of this difference was shown in the hearing before the Labor Board some time ago when the four brotherhoods brought up the question of wages.

Mr. Lauck, the attorney for these brotherhoods, brought in a brief which was very ably worded and thoroughly arranged. It purported to show that, while wages had increased approximately 100 per cent on the average, industrial returns had increased from 3 to 500 per cent on the capital. This brief was worked out so thoroughly that very few manufacturers would be possessed of sufficient information to refute the arguments and statistics contained therein. Mr. Lauck is a very prominent figure in labor circles. His arguments have been used and reused in the publications reaching labor and in the union meetings.

This is only one instance of the kind of information which the worker is securing in respect of the relation between wages and profits and between wages and cost. The information which has been given to the workers on this matter has been worked out more ably and carefully than any information from other sources and certainly it has been of far greater interest to them than any information supplied by their employers.

But this is not the most important reason for the attitude of the worker under present conditions. The fluctuations in wages are very much more personal to the worker in their appeal to his comforts and discomforts than the fluctuations of profit to the owners of industry and the executive.

One of the men in labor circles who has been a constant advocate of the retention of the present wage schedule by workers, mentioned a manufacturing concern the other day in connection with some disagreements. I said to this man, "How do you expect to get anywhere with your plans? That concern is almost down and out." He said, "Maybe it is, but I notice that the heads of the concern still own two or three automobiles and they still have their summer cottages and town houses, and they are still able to live in about the same comfort they did previously. They are still maintaining their executive organization in about the same way. The concern may be down and out, they are not. Why should the workers in the factory have to cut out some of the few comforts they have acquired and be the only ones to suffer in that way." To the worker this is a very strong argument. He lives from week to week, when his wages are good he secures a little extra comfort and he is not in the least likely to let that extra comfort slip without some struggle to retain it.

No man receives a cut in his earnings without raising some kick about it, and no man who studies the matter can expect his working forces to accept a

cut because business is bad, as long as there is the slightest chance to hold it.

No man who is in any position of responsibility in industry will accept a cut in his earnings without the idea that he will replace that cut as soon as business improves. The worker who is expecting a reduction in his pay to-day is expecting it on the basis that just as soon as business improves he will replace it if he can.

Any man who will study his own personal reactions will know that he cannot expect any other man to do what he finds it impossible to do, reduce earnings without complaint and without a distinct determination to get them back whenever it is possible. Any other contention or idea is absurd, and the idea expressed in this letter that manufacturers feel co-operation has received a body blow because of this reaction of the workers is equally absurd. This attitude as a matter of fact is in line with our general attitude on all matters which lie outside our personal relations.

We are very much more interested about the injustices of the other man toward us than we are about our own weakness in the same respect. It jars us pretty hard to be treated badly by some one else, while at the same time we are ready to excuse our own defects of the same kind. The worker is no different from anybody else, in that he desires to seize as much advantage as he can and retain it as long as he can. If he loses anything, he will try to get it back.

There is only one qualification to this statement and that is where he has become convinced of the squareness and understanding of the employer by long association, so that he is willing to play the game with him, believing that he will get back what is fair as business improves.

There are several isolated instances in industry where the workers have accepted a reduction and one or two where the workers have suggested a reduction. There are several instances where the workers have accepted a three-day week in order to keep all the workers employed to some extent. These instances occur because in those establishments the long association has been of such a character as to convince the workers they can expect a square deal and it is worth while for them to play the game all the way through.

The average worker does not believe that the manufacturer is suffering to any extent which need concern him. The newspapers he reads do not agree upon this, most of them discuss the reduction of wages as though it were the arbitrary decision of the manufacturer and had little or no relation to the cost.

Able men from union ranks and other interested organizations have written much which tends to prove in his mind that manufacturers have always received more profit than the worker and he is not inclined to waste any sympathy on the manufacturer over the troubles of the owners of industry. Neither is he in the least inclined to forego any advantage he has gained in wages unless he is obliged to, and then only under the impression that he will secure it again when business improves.

On the other hand, the manufacturer is frequently improperly informed as to the relation between the labor costs and the selling price in his own business, and is inclined to demand a reduction in wages because of the reduction in the selling price without any further analysis of the matter.

The manufacturer who desires to establish the same efficiency in his human relations which he expects in the development of his mechanical equipment, must be prepared to lead in fairness and square dealing just as he is prepared to lead in mechanical knowledge for the development of the other side.

Investment in time and experimentation to secure the right relations, can be no less than the investments in time and experiment demanded for mechanical improvement. He should know that this investment is much greater, and that a part of the study and development means the understanding of the worker better than the worker understands himself.

No man who understands the worker would expect him to accept a cut without kicking about it and without a desire to overcome it, and no man can expect the worker to believe, where he has no knowledge, or to drop his suspicions and play the game to his own disadvantage where he is ignorant of the effect which it will have.

Preparing for More Motor Vehicles in Tennessee

[From Department of Highways, Nashville, Tenn.]

THE Tennessee Highway Department is constructing highways both on the State aid and Federal aid plans. Aside from these highways, all the counties are constructing highways with funds derived from automobile license fees, county wheel taxes or county bond issues. It is impossible to secure any authoritative data on funds expended by the counties.

The following is a summary of State aid work under construction and in various stages of completion:

Type	Miles	Estimated Cost
Grading only	33.86	$139,194.26
Macadam	16.00	29,401.08
Chert	8.4	80,531.25
Concrete	2.5	130,200.20
Bridges	....	34,539.23
Total	60.76	$413,866.02

The 1921 Federal aid program consists of 271.75 miles of highways surfaced with the various types and having an estimated cost of $8,575,900, and bridges estimated at a cost of $370,000.

The following is a summary of Federal aid work under construction:

Type	Miles	Estimated Cost
Grading	20.47	$73,837.10
Macadam	84.68	1,430,064.87
Chert	30.45	470,312.49
Bituminous macadam	160.43	2,852,366.47
Rock asphalt	46.57	1,465,639.19
Bituminous concrete	7.43	261,639.19
Concrete	26.52	1,006,308.60
Bridges	....	32,467.21
Total	376.55	$7,753,541.27

Force account work on a day labor basis is being done on three macadam projects aggregating 16.77 miles.

One concrete highway project, 10.14 miles in length, is being constructed by county forces, under supervision of engineers of the State Highway Department, at fixed unit prices, making it essentially a contract job with the county as the contractor.

The remainder of the work is being done on a contract basis.

Export Selling

NOW and then, it is possible to show graphically some of the merchandising efforts attempted in export selling. The following translated paragraph from a letter written by an automotive dealer in Mexico is one of such cases:

"I am well satisfied with the catalogues and the correspondence I have been getting and only deplore that practically everything is in English."

This dealer, who speaks no English and who lives in a smaller city where it is not so easy to obtain English translations as it might be in Mexico City, Vera Cruz or Tampico, had requested catalogues and service information from American automotive manufacturers, particularly on cars and tractors.

The result, as shown by the letter, is especially disheartening in view of the present efforts being made by American manufacturers to distribute their lines through that country. An opportunity has existed in Mexico during recent months for automotive expansion that should have called forth at least the best efforts of every manufacturer who is sincerely desirous of building up and holding a large foreign business. But to realize on an opportunity such as this, should call forth the proper preparation by manufacturers and exporters.

Taxes! Taxes!!

SENATOR HARDING will be inaugurated President a week from Friday.

He is expected to call an extraordinary session of Congress to convene March 14.

Less than a month after the session convenes the House Ways and Means Committee will open its hearings on the question of Federal taxation.

Unless its present temper is radically changed, the congressional leaders will insist upon additional taxes on passenger-carrying automobiles on the ground that they are luxuries. The taxes proposed are unfair and almost confiscatory in their nature.

In addition to a prospective increase in Federal taxes it is almost certain many of the State Legislatures will enact laws which will impose additional tax burdens on an industry already overloaded.

The automotive industry is the second greatest in the United States. Its potential influence in Congress and in State Legislatures is tremendous. It should seek no favors, but it should object to being made the football of politics and taxation.

The only way heavily increased taxes can be averted is by concerted action on the part of the industry as a whole. If it makes the right kind of fight at least a part of these unfair taxes can be avoided.

Legislators, state and national, cannot be influenced unless a cannon, rather than a shot gun, is trained on them. They will take the easiest way, which is to tax automobiles—if the various branches of the industry begin shooting all over the lot instead of trying to hit the bull's eye.

With less than two months in which to map out a definite program and act, no steps have been taken to formulate a platform upon which every organization interested in automotive vehicles can stand.

Unless all organizations which are a part of the industry get together and act together, they will wake up some fine morning to find a few more taxes have been piled on their shoulders.

Legislation, state and national, never was more important to the industry than this year. The Motor Vehicle Conference Committee, through state committees, is watching state legislatures. The National Automobile Chamber of Commerce is on watch at Washington, but it is not exerting all its great influence to act in harmony with other organizations.

The directors of the Motor and Accessory Manufacturers' Association, at a meeting here Friday, decided to table the tax question because of the pressure of more important business. Their next meeting will be held late in March. Hearings on taxes will begin a fortnight after that date.

The industry is making no definite effort to prevent the flooding of the country with American made automotive equipment and supplies bought for a song in foreign countries.

The industry is making no definite effort to prevent the War Department from dumping scores of thousands of automotive vehicles of all kinds on the market.

If every member of every automotive organization was to send a telegram of protest to the legislators who represent him, legislators would at least know that the sender would hold him accountable for classing motor transportation as a luxury and taxing it accordingly.

Isn't it time for the automotive industry to prove it can work in harmony to prevent unfair, unjust and discriminatory legislative action?

If half the things planned are done to it, the recovery of the industry will be retarded for many months—perhaps years.

Parts Business in the Motorcycle Industry

ACCORDING to our British correspondent, British car manufacturers consider it rather beneath their dignity to use stock parts, and consequently there is no such thing as an assembled car manufacturer in Great Britain. In the British motorcycle industry, however, a large percentage of the manufacturers use stock parts or units such as engine or gearset, even some of the larger makers finding it economical to purchase these parts rather than manufacture their own. As a result many small makers who could not survive at all without the parts manufacturer are able to do a good business.

In this country quite the reverse condition obtains. A considerable proportion of our car builders do not fabricate any of the major units which make up the vehicle, but simply assemble the units which a specialty manufacturer, with large output, is able to sell them at a price which enables competition with even the large producer whose business is sufficiently large to enable him to build all or most of the component car units to advantage. The same is true in the truck and tractor fields, but strange to say is not true in the motorcycle industry. There seems to be no inherent reason why a motorcycle parts business could not be built up if proper initiative and thoroughgoing methods are applied. It is at least a possibility which is worthy of study by manufacturers who are seeking an opening in the automotive field.

Excess Profit or Surtaxes

A FINANCIAL man recently declared that it was not the repeal of the excess profits tax that was needed, but the repeal of the surtaxes on incomes.

He said that the great need of to-day is for more money with which to conduct business. This money in the past, said the financier, came from persons with large fortunes, who were constantly seeking new fields of profitable investment. Since the war closed, these persons have been engaged in transferring their investments to tax free securities. As rapidly as possible persons of large income had been selling the ordinary sort of securities. It has been the job of salesmen of securities to find new capital to absorb these securities. This new capital has been found in the investor with a comparatively small income, but the new investor's power of absorption is not equal to carrying such a heavy load as is now offered to him. Already this investor has a large capital in Government bonds and is increasing daily his investment in industrial securities of the highest types, but the investor of large income is shedding too rapidly for him. So anxious is he to avoid the surtax that industry is handicapped in its effort to secure capital.

It is surprising how many of the common people one finds who believe that a limit on company profits is a pretty good thing. The average person probably has an exaggerated idea of how much profit companies make, and they are not much educated by the annual statements of these companies. Usually these tell nothing to the public. When the casual reader sees in these reports a careful restraint in the way of saying anything about excess profit taxes, he suspects that the taxes were so large as to need concealment.

Anyway, the excess profit taxes probably will not be much of a bother for a few months, so why not get rid of the surtaxes?

Using Higher Compressions

THOSE interested in bettering the thermal efficiency of automotive engines should study the article by Mr. Ricardo in this issue.

For several years past there has been a tendency toward lower compression ratios which some think were forced upon us by the inclusion of less and less volatile elements in the average fuel available. This is, of course, a tendency toward lower efficiency, hence it is refreshing to hear a word now and then about the use of higher compression and higher expansion ratios—even higher than were used when fuel that didn't produce a knock was available in abundance.

Perhaps the easiest way to adapt the engine to the fuel was to lower the compression, but it is evident that it was not the only way and certainly a very poor way from the standpoint of economy. Diluents which prevent excessive pressures and temperatures have been tried with varying degrees of success, depending upon their nature and proportion. Some say that diluents, such as benzol, which in themselves possess fuel value will never see very extensive use because they are not available in sufficient quantity. Inert gas such as exhaust products can be used to advantage in some cases as Mr. Ricardo shows. But perhaps the most promising diluent, at least within certain limits, is pure air, especially when used under part load conditions in such a way as to maintain high compression and thus avoid throttling. To do this requires some but not extensive alterations in the conventional type of automotive engine (as we propose to show in articles soon to appear in AUTOMOTIVE INDUSTRIES). The problems involved are not completely solved, but do not seem by any means insuperable, and the advantages are of such great significance as to make the effort at solution well worth while.

Army Starts Sale of Surplus Cars

Unserviceable Stock First to Be Cleared

Twenty-nine Thousand Vehicles Booked for Auction—Deny Undisclosed Supplies

WASHINGTON, Feb. 18—Orders have been issued to all departments of the United States Army to dispose of surplus automotive equipment which it is officially estimated will amount to approximately 29,000 unserviceable vehicles. The sales campaign which was inaugurated at Camp Holabird, Baltimore, this week, will be nation-wide though the vehicles will be concentrated at four camps now under the supervision of the Motor Transport Corps of the Army. Unofficial though apparently authentic information to the effect that general orders calling for the disposal of all vehicular equipment, retaining only 30,000 vehicles in this country, insular possessions and in Europe, was denied at the War Department today.

This unheralded movement on the part of the Army has resulted in protests to Congress and the Secretary of War from automobile dealers associations and chambers of commerce. The War Department has taken little cognizance of the protests from business men and, it is said, will continue its program of selling 29,000 automobiles, trucks, motorcycles, tractors and bicycles.

Practically all this material is now unserviceable, the War Department advised AUTOMOTIVE INDUSTRIES to-day, and because of the large sums required to put the stock in service, they point out that it will have little effect on regular dealers and will boom business for garages and dealers selling accessories. Dealers, however, contend that the net result of this flood of vehicles will be disastrous because prospects for new machines will take advantage of ridiculously low prices accepted by the Army and take a chance on a small repair bill.

Censor Inquiry Results

AUTOMOTIVE INDUSTRIES was informed to-day that the inquiry undertaken by the Inspector-General under orders from the Secretary of War brought out some startling facts. It is claimed that two unlisted warehouses were discovered near Newport News which contained several hundred uncrated automobiles, trucks and ambulance bodies, which had been stored with a view to easy loading when needed in France. These machines are deteriorating rapidly owing to climatic changes but it is averred that the majority of this lot is ready for service after slight repairs. Officials of the Motor Transport Corps refused to confirm this statement.

Recent attacks in Congress directed at the War Department for the misuse of automobiles purchased for war purposes has resulted in establishment of a censorship. This information was obtained from authoritative sources, however. The Inspector General's survey was caused by the introduction of numerous bills in the Senate and House directing the War Department to turn over all surplus automotive equipment to the highway departments.

The story is current and officially confirmed that special orders were issued recently to departmental commanders to prepare charts based on the reduction in the size of the Army as authorized by recent legislation. These charts were to cover the amount of automotive equipment and other vehicles considered absolutely essential to the maintenance and transportation of the troops in each Army post throughout the world. Army officials deny, however, reports that the analysis of the charts received here indicated that there would be from 200,000 to 300,000 vehicles of all types, motor and horse-drawn, which would be offered for sale as surplus.

The Transportation Division of the Army informed AUTOMOTIVE INDUSTRIES that approximately 103,000 automotive vehicles were in France during the years of the war and about the same number bought and in service in this country. They pointed out that thousands of vehicles were rendered useless in service and a large part of the remainder sold abroad rather than disrupt American markets.

Under existing legislation, the War Department has been disposing of automobiles, trucks and tractors by transfer to the Postoffice Department, the Bureau of Public Roads and the Public Health Service.

Army Reduction Makes Surplus

Tentative measures pending in Congress would require the sale of 10,000 trucks, 1000 automobiles, and 2000 tractors. The reduction in the Army brought about a natural surplus without the stimulation of legislation. The War Department claims that all Government agencies have first choice of surplus automotive equipment before it is offered for sale at auction. The Bureau of Public Roads asserts that the War Department has frequently declined to transfer equipment needed for highway construction on the ground that no surplus was available.

Congressman Anthony of Kansas had ideas of his own and declared that the highways could not absorb additional equipment and imposed a provision in the Army appropriation bill to compel the sale of not less than 10,000 trucks

Baltimore Buyers Pay $40 to $2,400

2100 Light Delivery Cars, Trucks and Ambulances Sold in First Allotment

BALTIMORE, Feb. 21—Despite a protest by the Baltimore Automobile Trade Association to the Government asking that the sale of used motor vehicles in large quantities be discontinued in Baltimore, officials of the Government sold last week 2100 motor cars of all kinds and in various conditions.

No touring cars were offered, the models being light delivery cars, trucks and ambulances. A crowd that ran into thousands was on hand throughout the sale and the machines were sold at a very rapid rate. For a time the average was about two a minute.

Inspection of the cars by buyers was limited to a look under the hood and a moving of brakes and gears and any other exterior inspection possible, but no cars were permitted to be tested as far as operation was concerned.

Government officials stated the cars were serviceable, but did not come up to the specifications demanded by the Government. All the machines that left Camp Holabird, the Government camp a few miles from the city, were towed away.

The cars being sold here are used motor vehicles gathered from the various motor camps of the United States. They are being sold under the authority of the Quartermaster-General's office and officials of the Motor Transport Corps directed the sale. Buyers came from all over the country. It is estimated that the first day's sales totaled $200,000.

On the second day some of the big trucks brought as high as $2,400. The lowest price was $40.

Purchases Range to $20,000

Interests said to represent the General Motors Corp. and the Backus Motor Co. of East Orange, N. J., are reported to have purchased about $20,000 worth of cars each.

Brigadier-General A. E. Williams, assistant to the Quartermaster-General, attended the sale and was accompanied by Colonel F. H. Pope, chief of the Motor Transport Corps, and Lieutenant-Colonel W. N. Haskell, assistant director of sales.

Practically none of the cars leave the grounds under their own power. About 300 freight cars of the B. & O. and Pennsylvania Railroad now are parked just outside the grounds ready to receive the cars for out-of-town shipment.

Production Grows as Sales Expand

Paige Sets Schedule of 1,500 for March

Reports Orders for 800 Cars on Books—Packard Sales Show Increase

DETROIT, Feb. 18—Optimism engendered by enthusiasm at the national shows and which was discounted to some extent by more conservative manufacturers, who attributed it solely to stimulation of the exhibitions, has cropped out anew this week as the result of actual sales recorded and orders to parts manufacturers. A sharp upward trend is noticeable.

While the improvement, in the minds of many, is attributable in great measure to weather conditions, which naturally have a tendency to hurry the spring demand, others insist that it presages a return to real business and predict a steady improvement that by mid-summer will find the industry in pre-war normal condition. Outstanding evidence is the attitude of the Paige-Detroit Motor Car Co., which now is on a schedule of 40 cars a day, operating four days a week with the plant's entire force of approximately 3000 men. According to Paige officials there are 800 actual orders on the books, and a production schedule of 1500 cars for March has been outlined.

Paige dealers throughout the country, according to factory officials, report an inclination on the part of the public everywhere to assume a buying attitude, and while actual orders have shown no great spurt, there is every indication, dealers say, that brisk spring business will begin during March and increase steadily.

Packard Ready to Expand

The same optimistic report was given out by officials of the Packard Motor Car Co. In fact, it was said at the Packard plant that the average for the present week was far in excess of that for the same week last year in point of actual orders. The Packard plant is operating with only about 1000 employees and building approximately 25 per cent of the normal schedule. Packard officials say if sales continue to increase in the next few weeks as they have in the last two, the factory force and output will have to be materially increased.

Fred Glover, general manager of the Timken Roller Bearing Co., expressed himself gratified with the signs of improvement. His company, Glover said, had received orders in much better volume for February, while the great improvement in orders for March clearly indicated that the return to normal would soon be under way vigorously.

GOODYEAR SCHEDULE INCREASED TO 60,000

AKRON, Feb. 22—The Goodyear Tire & Rubber Co. to-day went on a production basis of 60,000 tires weekly increasing from 38,000 and increasing the operating time from four eight hour days each week to five eight hour days a week, with no additional men being put on. This is the first substantial increase in production announced by any Akron rubber company and is the first increase by Goodyear since the beginning of refinancing negotiations. The company at its peak last summer, was making 33,000 tires daily in the Akron plant. Goodyear's announcement, coupled with a shipment of 30,000 tires to Henry Ford by the Goodrich company indicates a steady upward trend in the tire industry.

Continental Motors Adds 1,000 to Force

NEW YORK, Feb. 21—Business of the Continental Motors Corp. is increasing, according to an optimistic statement on the business outlook made by G. W. Yeoman, vice-president and treasurer of the company, in response to a request for information made by Sidney S. Meyers, general counsel of the Motor and Accessory Manufacturers' Association. After pointing out the impetus given by the New York and Chicago shows, Yeoman said that nearly 1000 men have been added to the force employed in the Detroit plant to get out this month's demands and that orders for delivery for March will be from 30 to 40 per cent greater than February.

"If anyone tells you this is only a little spurt and that the demand will decrease, tell them they are crazy," said Yeoman. "Sixty to 90 days from now the automobile business, through the possibilities of liquidating large stocks of inventory, should be in a very advantageous position to again establish itself on a cash basis. The sale of trucks has not yet started in any volume, although we have orders on hand from about 60 per cent of our customers for shipment the latter part of February and for the months of March and April.

Necessary as Foodstuffs

"Our entire organization is of the firm belief that the automobile and truck industry is built on a strong foundation and that its products are as necessary to the upbuilding of this country as the raising of foodstuffs and other so-called staple articles."

Kalamazoo Plants Increase Operations

Definite Increase in Business Experienced Since Shows—See Complete Recovery

KALAMAZOO, MICH., Feb. 21—"Just as it has in times past, the automobile industry will lead business in this country back to prosperity" said Christian Girl, president of the C. G. Spring Company, during a discussion of the outlook for business in the near future.

"Distribution is still the weakest link in the chain of American industry" added Girl. "It is the close affiliation of the automobile with the problems of distribution and the need of motor cars and trucks to solve these problems that will tend to a steady revival of the automobile business. This revival will not be an over-night affair like the recent suspension. It will come gradually.

"We have suffered from a hard fever. While we no longer have the fever, we are weaker than when the fever raged. It will take time to convalesce, but recovery is certain. I look for over 50 per cent production this year and normal business in 1922."

The C. G. Spring Co. is already feeling the effects of the coming better times. Inquiries are common and many substantial orders are being booked. The working force will be increased steadily as business requires. This also applies to other Kalamazoo manufacturers allied with the automobile industry. The recent depression is gradually disappearing and is being succeeded by a feeling of optimism.

"We are now running about 60 per cent of our capacity" said J. D. Bobb, president of the Limousine Body Co. "I look for a substantial increase in business by spring.

Substantial Orders Received

"The outlook is flattering" said F. P. D'Arcy, president of the D'Arcy Spring Co. "During the past few days we have received several substantial orders and the inquiries at hand indicate there will be plenty to do later on. Our plant is now operating on about 33 per cent capacity, but the number of employees will be steadily increased. The fact that we intend to reorganize and recapitalize indicates that we are looking for a larger business in the future than in the past."

James I. Handley, president and general manager of the Handley-Knight Co., reports orders on the companies books for over $250,000, all to be filled by April.

"Conditions have improved greatly

St. Louis Estimates 750 Sales at Show

Total Business Done Is Expected to Exceed $1,000,000—Attendance Mark Highest

ST. LOUIS, Feb. 18—From the viewpoints of attendance, merchandising, sales and the procuring of prospect lists, the fourteenth annual automobile and accessory show, held in this city last week, was without question the most successful of all St. Louis exhibitions, according to Robert E. Lee, president of the St. Louis Automobile Manufacturers and Dealers Association, and manager of the show.

Every exhibitor reported sales daily, almost from the time the doors were opened. An incomplete analysis of the business consummated during the week make a total of approximately 750 cars sold. Considering $1,500 as an average price, the total will surpass the million dollar mark. This represents an increase of a minimum of 10 per cent over the sales negotiated during the 1920 exhibition, according to Lee.

The total attendance, including the record breaking crowd of 22,000 on the opening night, amount to a 20 per cent increase over last year's show and reached 105,000. This is the greatest number of persons ever attending a St. Louis automobile display. "An outstanding feature of the show is the fact that exhibitors obtained prospect lists much larger than those recorded during previous shows," said Lee. "This proves that the public is again in the buying mood and the fear of continued business depression is allayed."

Because of the unusual interest which the public showed during the exhibits last week, the dealers are predicting that during the spring months there will be a shortage of cars. On Feb. 1 the St. Louis association in making its monthly canvass of the number of unsold motor cars in the city, found that the stock was far below that which the dealers usually carry at this time of the year.

Stock Accounting Asked in New Templar Suit

COLUMBUS, Feb. 19—N. P. Clyburn, former prosecutor of Ross County, now a resident of Washington, has brought suit in the Franklin County Courts asking for a receiver for the Templar Motors Co. of Cleveland. Included in the action is a complaint against M. F. Bramely, president of the Templar Co., and W. O. Cooper, head of the W. O. Cooper Co., the stock selling agents, for an accounting on the allegation that the two named persons received $2,500,000 or thereabouts for the sale of stock illegally. Former Attorney General F. S. Monnett of Columbus is plaintiffs' attorney.

B. Pittman, formerly sales manager, who is now in the brokerage business in Columbus, brought a similar suit against the corporation and officers, but it was dismissed. Several indictments have been returned against Pittman, one of which is for the embezzlement of $200 and another for circulating a circular tending to reduce the value of stock. This is the result of a circular issued telling of the alleged illegal financial transactions of the company. The annual stockholders' meeting of the Templar Co. is scheduled for March 1.

Sales Sentiment Grows Throughout Country

WASHINGTON, Feb. 21—Business conditions will improve from now on, says Archer Wall Douglas, chairman of the Committee of Statistics and Standards of the Chamber of Commerce of the United States, in his monthly review of business issued to-day.

"The most convincing evidence that we are on the high road to recovery," Mr. Douglas said, "is found in the universal report, brought by traveling salesmen from every section of the country, of steadily growing sentiment that business will be better in the spring—not a sudden return to prosperity, which is neither likely nor desirable, but a slow and natural working out of those processes of liquidation which are now in full operation."

Gasoline Prices Drop Six Cents in Mid-West

NEW YORK, Feb. 21—Gasoline prices have been reduced from 1 to 6 cents a gallon in the principal cities east of the Rocky Mountains, but no reductions have been made as yet on the Pacific Coast. Reductions of 3 cents have been made throughout the eastern territory and of 4 cents in the middle west. In the midcontinent and southwest territory prices have declined in some cities as much as 6 cents a gallon from the peak of 1920. The lowest price is in Kansas City where it is 21 cents a gallon, with St. Louis second at 22.5 cents. Chicago and Houston, Tex., are tied for third place at 23 cents. The price is highest at Butte, Mont., where it is 31 cents.

DISCUSS TRUCK PARTS SERVICE

CHICAGO, Feb. 24—A committee of the Motor Truck Manufacturers Association consisting of O. Armleder of the O. Armleder Co., M. Cook of the Service Motor Truck Co., and J. W. Stevenson of the Indiana Truck Corp., will meet with representatives of units and parts makers at the Hotel La Salle here to-day to discuss with them the subject of establishing their own distributing and service stations. This meeting was scheduled for Detroit on Feb. 18 but was postponed.

COLUMBIANA RECEIVER ASKED

EAST LIVERPOOL, OHIO, Feb. 21—A petition has been filed at Lisbon asking for the appointment of a receiver for the Columbiana Rubber & Tire Co.

Medium Priced Cars Lead New York Sales

General Improvement Noted in All Classes—Dumping Slows Truck Sales

NEW YORK, Feb. 21—More motor cars were sold in New York during the past week than in any similar period in several months. The upward trend of the market is not confined to any particular car, or class of cars. The return to buying has been general and for the first time in many weeks there is a distinct demand for cars that is evidencing itself in many ways.

The largest sales increase was made in the medium price class. Three dealers in this class reported sales for the first 18 days of February to be 33⅓ per cent above the same period in 1920. While several of the others did not approach this mark, all had experienced increased business.

There also was an appreciable increase in the demand for the higher priced cars. Most of the "quality class" dealers reported business increases that were distinctly satisfactory.

In this class, as well as in the medium priced car class, there was a marked increase in the demand for open cars. Early spring delivery orders in open models in the higher priced cars were particularly noticeable.

While there is no marked improvement in the truck market, there is evidence of an early upward trend of the extremely low sales record. The truck dealers are watching closely the effects of the sale here of some of the A. E. F. equipment in the past few days. It is felt that the natural spring demand for trucks may be somewhat diluted this year if these trucks are dumped on the market.

There has been little appreciable demand for used cars, although the market is slightly better. Some of the dealers have had inquiries for used cars for export to Belgium and a few lower European countries.

AUTOCAR ADDS TWO DIRECTORS

PHILADELPHIA, Feb. 21—The board of directors of the Autocar Co., Ardmore, Pa., has been increased from seven to nine by the addition to the board of J. Howard Reber and Roscoe T. Anthony. The other directors were re-elected and they in turn re-elected the old officers. David S. Ludlum is president of the company.

EVERED SOLD TO TWIN PORTS

SUPERIOR, WIS., Feb. 21—The Twin Ports Steel & Tractor Co., which was incorporated recently with $250,000 capital, has taken over the entire business and works of the Evered Foundry & Machine Works here. It will continue the manufacture of gas tractors, hoisting engines and power winches, but will also take on jobbing orders for pattern, casting and machine work.

Trucks Find Place At Machinery Shows

Manufacturers Encouraged by Roads Exhibit Results, to Take Mine Show Space

CHICAGO, Feb. 19—Although manufacturers have not been disposed to stage a separate truck show in this city, they are at the same time taking advantage of every opportunity to put their product before the public through the medium of other shows into which a display of motor trucks fits well. This was shown in their use of the Good Roads Show.

A still truck show, it has been felt, lacks the magnetic power that a show in motion has, and the manufacturers saw in working machinery, such as that used in road building, this desired touch. Thousands of road builders attended the good roads show and while their interest did not center in the trucks when they came, nevertheless they could not help but see them once they were there.

Now comes another show, the mining machinery show, which is to be held in Chicago some time in the fall and possibly on the Government pier. Manufacturers appealed to the good roads builders with their exhibits of last week; in the fall they will send forth their message to the mine operator and show him, just as they showed the road builder, how essential the motor truck is in his line of business. The approaching mining show will be a show in motion, just as the good roads exhibit was, and the truck manufacturer will make capital of it.

Wisconsin Factories Resume on Large Scale

MILWAUKEE, Feb. 21—Passenger car manufacturers in Milwaukee and Wisconsin are steadily increasing working forces in order to handle current orders for immediate and near-future delivery. In Milwaukee, the four-cylinder division of Nash Motors Co., Kenosha, which was down for several weeks, is employing more than 400 men. The Milwaukee assembling plant of Ford has resumed work and is rapidly reaching its normal schedule of 115 cars a day. Manufacturers of automotive materials, parts and equipment likewise find conditions more encouraging and are making gradual increase in working forces and output. A considerable number of men have been notified to report for work March 1 and 15, and in the meantime a few men are being taken back every day.

SIEMON SELECTS ROCHESTER

ROCHESTER, Feb. 21—Assurances that the Siemon Tractor Corp. will establish its plant in Rochester have been given to the industrial development committee of the Chamber of Commerce here. Negotiations have been in progress for the past few weeks between the chamber and the officers of the company which has been in existence for three years. An extensive investigation of the tractor, the cost of manufacture, the probable market for it and the financial situation in which the company finds itself, all has been investigated.

J. C. Siemon, president of the corporation, is a business man well-known in Canada and Buffalo. A number of prominent Rochesterians have interested themselves financially in this company. President Siemon announces, however, that additional capital will be needed to establish the plant in Rochester. He is looking for quarters for a site at the present time.

Briscoe Schedules 12,000 for 1921 Production

DETROIT, Feb. 18—Waring Sherwood, advertising manager of Briscoe Motors at Jackson, in reply to rumors that the plant was about to shut down, has authorized the statement that Briscoe is rapidly getting to normal production, and expects to reach that point by April 1.

"Our plant has not been shut down at all," said Sherwood. "We have never at any time had less than 500 men working, and we have put on 40 additional men. We are building from 15 to 20 cars a day, and plan to increase our force and output steadily until by April 1 we expect to be turning out 50 cars a day. We have outlined a schedule of 12,000 Briscoes for 1921, and have every reason to believe we will carry out that schedule.

"There is every indication of good spring and summer business, and our actual sales before, during and since the National shows, convince us that the automobile business rapidly is on the upgrade. Everything points to splendid business throughout the year."

TOOL APPLIANCE ORDERS GROW

PHILADELPHIA, Feb. 18—A marked increase in orders is recorded for the first half of February by the Standard Shop Equipment Co., manufacturers of set-up appliances for machine tools. This company does considerable business with automobile manufacturers, so that the increase furnishes another indication that business has started on the upgrade. There is no reason to believe this increase has been temporary.

AUTO-LITE ADDS 200 MEN

TOLEDO, Feb. 21—The Electric Auto-Lite Corp., a subsidiary of the Willys Corp., has called back to work nearly 200 former employees, making about 400 now employed out of a normal 3000. While the outlook for the future business remains uncertain, it is more encouraging than it has been.

BROCKWAY STARTS FULL FORCE

CORTLAND. N. Y., Feb. 21—The Brockway Motor Truck Co. has resumed operations with its full force of 200 employees. Preparations are being made for the enlargement of the plant.

Willys-Overland Bankers Organize

Protective Committee Formed Because of Close Association With Willys Corporation

NEW YORK, Feb. 23—Bank creditors of the Willys-Overland Co., Inc., have formed a committee headed by Ralph Van Vechten of the Continental and Commercial Bank of Chicago to protect their interests. The committee includes John Sherwin of Cleveland, Joseph Wayne, Jr., of Philadelphia, and several representatives of New York banks and banking houses.

The committee was formed because of the close relations existing between the Willys-Overland Co. and the Willys Corp. The affairs of the Willys Corp. have been taken over by a bankers' committee which is working in harmony with another committee representing merchandise and construction creditors.

The banks interested in the Willys-Overland Co. are by no means identical with those which have made heavy loans to the Willys Corp., and the Chase National of New York, which is probably the largest bank creditor of the corporation, is not represented on the other committee. It is understood, however, that the two committees do not conflict in any sense and that they will co-operate so far as possible for the good of the two companies.

The affairs of Willys-Overland are not involved directly with those of the Willys Corp., although 27 per cent of its common stock is owned by the corporation. It is understood that no refinancing is contemplated for Willys-Overland in the immediate future nor has any merchandise creditors' committee been formed up to this time.

Large blocks of the first and second preferred stock of the Willys Corp. have been deposited with protective committees which have been formed, and preliminary conferences already have been held with the bankers' committee.

KELSEY WHEEL PLANT STARTS

MEMPHIS, TENN., Feb. 21—Following an inactive period, the Kelsey Wheel Co., large manufacturers of wheels and automobile bodies, began a general resumption this week with 100 employees at work. Ten per cent capacity runs were started and from week to week a return to normal standards will be accomplished. The company employs about 800 men under normal conditions.

ALLEN RESUMES ON NEW ORDERS

COLUMBUS, Feb. 21—The receivers for the Allen Motor Co. have opened the Columbus factory, which was closed down recently for inventory, with about 100 men employed. Orders for a large shipment of cars were received recently and mail orders are coming in. The plant is being operated on about a 50 per cent basis.

Tariff Rule Hurts Cars at Paris Show

American Place Selection Follows British, Italian and Belgian —German Cars Barred

PARIS, Feb. 1—Regulations for the Paris automobile show, to be held in the Grand Palais from Oct. 5 to 16 next, provide for twelve classes covering the entire automotive industry, with the exception of aviation. On the main floor, which will be reserved to automobile exhibits, stands of 40, 60 and 80 square metres will be provided, with prices varying from 120 to 500 francs per metre, according to position. The rental of the best and biggest stands will, therefore, be 40,000 francs, and the smallest stand on the ground floor will cost 4800 francs. The above prices comprise electric lighting and all decoration.

Manufacturers belonging to Allied nations are admitted on the same terms as French firms, providing they have taken part in three previous Paris shows and on condition that their pre-war import duties were not higher than 15 per cent ad valorem. Under this rule American firms do not have the same choice as British, Belgian and Italian manufacturers. Special positions will be reserved for American firms, and for manufacturers belonging to nations who were neutral during the war. Late enemy nations will not be admitted.

The Paris show is handled by a committee composed of delegates from the leading French automobile trade associations, with Henry Cézanne as general manager. The balance remaining after all expenses have been paid will be disposed of as follows: Thirty per cent to be given to organizations existing for the benefit of the French automobile industry, and 70 per cent to be returned to exhibitors in proportion to the rental they have paid for their stands. Price of admission to the show will be 10 francs on the opening day and on Fridays, and 3 francs on all other days.

Requests for space should be sent to the offices of the organizing committee, 51 Rue Pergolese, Paris, not later than June 1, 1921. The drawing of lots for positions will take place from Aug. 1, but applications received after June 1 will only be considered after other requirements have been met. Exhibitors in the Paris show must undertake not to take part in any exhibition, race, or competition not approved by the National Automobile Federation.

Swiss Railroads Seek Truck Line Regulation

NEW YORK, Feb. 21—Dispatches from Switzerland say that the use of motor trucks for transporting goods in that country has become so extensive that the Swiss state railways have requested the government to take legal measures to prevent private firms from competing with them. Not only has passenger traffic on state railways been cut down by the use of private motor cars, but freight traffic has also been seriously affected by motor vans. Every time freight rates are raised more persons avoid use of the railways and the truck service has become a formidable rival for the transportation of goods, especially as they can provide door to door delivery.

One motor truck company proposes to establish a service between Italian and French ports and Switzerland, thus taking goods coming from the United States direct to Swiss warehouses on motor vans.

Receiver Is Appointed for American-British

NEW YORK, Feb. 21—George C. Van-Tuyl, Jr., has been appointed by Federal Judge Knox as receiver for the American & British Mfg. Corp., New York, in a suit brought by the American & British Securities Co., a creditor, for $37,516. The petitioning creditor is a Delaware corporation. Its claims are for money loaned, but it also holds 23,265 shares of the preferred stock of the manufacturing corporation and 31,277 shares of the common. The bond of the receiver has been fixed at $20,000.

The petition alleges that the defendant company is financially embarrassed, although it is considered solvent. It is stated that in the summer of 1919 the American & British Mfg. Co. entered into a contract to construct automobiles on a quantity basis and that in order to complete the contract it had to sublet certain parts of it. After making its agreements, a strike broke out in the plant of one of the sub-contractors, and because of this labor trouble, the business of the manufacturing company was put back for nearly a year, but it continued to manufacture other parts, and in so doing used up all its funds, which amounted to more than $1,000,000. This is stated to be the cause of the present trouble. Plants of the company are at Bridgeport, Conn., and Providence.

COMMITTEE TO DIRECT PREMIER

INDIANAPOLIS, Feb. 21—The board of directors of the Premier Motor Corp. has appointed a special committee to direct the affairs of the company because of the death of Dr. L. S. Skelton, president. This committee is headed by I. F. Schaefer and includes Newton P. Hutchinson, A. Follansbee, J. D. Sutherland, the Fletcher American National Bank and the George W. Goethals Co. The Goethals company has been retained to make a complete study of the Premier situation.

MERCEDES SOON TO ARRIVE

CHICAGO, Feb. 18—The new 6-cylinder Mercedes car is expected to arrive in this country in the next thirty days. It will sell for $10,500, chassis complete, and will be handled in the Chicago territory by the Mercedes Agency, 30 North Michigan Boulevard.

British May Change Yearly Show Plan

Annual Olympic Exhibit Loses Favor With Manufacturers— Not Justified by Trade

LONDON, Jan. 27—(*Special Correspondence*)—The statement which has been rife to the effect that the next Olympia car show is to be held *in September*, is at best premature, and most probably quite impossible of being realized. It would be nearer to the truth to state that a movement finds increasing favor *in the trade to forego the yearly show*, but it is not so *certain whether the view inclines to a more or less total abandoning of the show or to holding it in alternate* years, as in Paris.

Considering that cars are becoming stereotyped in design, that standardization bids fair to reduce varieties of types and makes, and, above all, that *the show is a tax on the industry*, it is not surprising that the matter of abandoning an annual show is becoming prominent in the trade.

Last year's show is reported to have yielded a normal year's profit despite much higher administrative and other costs. Nevertheless it was not justified by the trade it brought, so that on this account and others, it is not surprising that the movement against, at least a yearly show, is gaining support.

Dealers as a body, especially the leading ones, are averse from a yearly show. They say that they can do all their business locally, and that the show period tends to disturb normal business. Manufacturers who dissent from the yearly show ideal say that its purpose so far as it is a means of financing the trade society can be accomplished by a levy on members, varying with their turnover and output or some other reasonable means of assessment.

DUDLO EXTENDS PLANT SITE

FORT WAYNE, IND., Feb. 19—The Dudlo Co., which in normal times employs about 1000 men, has announced the purchase of six acres of ground adjoining its present plant upon which additional buildings will soon be erected. The company makes insulated wire for automobiles and other automotive products. Its principal customer is the Ford company. At the present time the plant's departments which work on Ford material are shut down.

DUPLEX OFFICERS ELECTED

BEAVER DAM, WIS., Feb. 21—At the annual meeting of the Duplex Storage Battery Co. of Beaver Dam, Wis., a $1,000,000 corporation manufacturing storage batteries, the following officers were elected: President, John W. Deniger; vice-president, John V. Zweck; secretary and general manager, Peter M. Kettenhofen; treasurer, M. A. Jacobs. The directorate was increased to two members.

S. T. D. Enter 3 Cars For Indianapolis

Sunbeams and Talbot-Darracq to Be Driven by Boillot, Resta and Thomas

PARIS, Feb. 5—(*Special Correspondence*)— The European representative of the Indianapolis Motor Speedway Co. has received the official entries of one Talbot-Darracq and two Sunbeam cars for the next 500-mile race on the Hoosier track. André Boillot has been selected to drive the Talbot-Darracq, and Dario Resta and René Thomas will be at the wheel of the two Sunbeams. All three men have had previous experience at Indianapolis; Thomas and Resta each having finished first and second in previous races. Until this year André Boillot was a member of the Peugeot team.

The Talbot-Darracq and the Sunbeam cars form part of the Franco-British syndicate known as the S. T. D., comprising Sunbeam, Talbot and Darracq. There is one experimental department, under the control of Louis Coatalen, for the three firms, and the racing cars are consequently all of one design. The Sunbeams, however, have been built at Wolverhampton, England, while the Talbot-Darracq are being produced at the Darracq factory, near Paris. For the first time eight cylinder ahead engines are being built, the bore and stroke being 65 by 112 mm., which brings the piston displacement just inside the 3-litre limit.

Louis Coatalen, who will accompany his team, states that the cars will be rushed back to France immediately after the Indianapolis race in order to take part in the French Grand Prix at Le Mans, on July 24. In the French classic the S. T. D. combination will have seven mounts, as follows: two Sunbeams, drivers André Boillet and René Thomas; three Talbot Darracq, drivers Zobrowski, Seagreave and H. J. Cooper, and two Talbots to be handled by K. Lee Guinness and D. Resta.

Moto-Meter Establishes European Production

NEW YORK, Feb. 21—Arrangements for the establishing of branch factories of the Moto-Meter Co., Inc., of Long Island City, in England and France, have been made by President George H. Townsend and E. V. Hennecke, the sales manager, who recently returned from abroad. The Benjamin Electric Co., Ltd., of Tottenham, London, will have charge of the manufacture in England, and the French factory will be conducted at 50 Avenue de la Grand Armee, Paris, by F. Represseau et Cie. Both factories already are in operation.

A Canadian factory will be operated at Hamilton, Ont., under the direction and supervision of the home office. S. E. Ryder will be in active charge.

Money Need Hurts British Industry

Austin Would Defeat American Competition With Increased Capital—Trade Has Bad Name

LONDON, Jan. 27 (*Special Correspondence*)—Sir Herbert Austin, M.P., head of the Austin Motor Co., at a meeting this week of Austin stockholders held that the British industry *is under capitalized for current and future needs. He said if it had* $125,000,000 *it could build cars just as cheaply as Ford, and that competition in the future with British cars would be less from America and more with European countries.*

He admitted that the motor trade had "a bad name" among city interests, but could see no justification for the fact. He referred also to what he considered the unfair competition the British makers have to face in foreign countries and in British colonies, and stated that *there were thousands of foreign cars at foreign and colonial ports awaiting disposal by auction.* Despite all these difficulties, he stated that some British firms were selling treble more cars than at the corresponding period before the war.

The position, said Austin, is that the industry wants more capital; the city investors think that it has had more than enough. It is for the public to decide. In other words, *it is a matter of restoring public confidence in the industry's prospects which, unfortunately, have been badly shaken by the failure of the trade to justify the post-war hope for its recovery.*

France Makes Changes in Regulations Governing Fuel Consumption Tests to Be Held at Le Mans

PARIS, Feb. 5 (*Special Correspondence*)—There will be a repetition of the French fuel consumption tests of last fall on May 14 and 15 next, when more scietific measures will be adopted than were possible for the initial test. The event will be held on the closed course at Le Mans, selected for the French Grand Prix race. It is 10½ miles round, and practically level. A distance of about 150 miles will have to be covered, but by reason of the shortness of the course it will be possible to maintain accurate control over the competitors.

This year's event will be open to stock cars only, cyclecars and motorcycles being excluded. Fuel will be given out to the competitors the day before the competition, and the cars will all be kept in a closed park until the time for starting. They will then be pushed to the starting line, and as the amount of fuel is calculated according to piston displacement and weight, the winner will be the one covering the greatest distance.

Among the changes are a minimum speed for each individual lap, and a speed competition on the day following the fuel trials, without any change being made on the carbureter adjustment. Last year all the competitors adjusted their carbureters for speed after the fuel trials. Any kind of fuel can be used.

Six classes are provided for, beginning with machines of 61 maximum cu. in. piston displacement and increasing to a class of more than 275 cu. in. The following table shows the minimum weight for each class, the minimum speed to be maintained, and the allowance of fuel, in American gallons, per 62 miles. Corrections will be made on this amount according to increases in weght and in piston displacement.

Class	Piston displacement cubic inches	Minimum weight pounds	Minimum speed miles per hour	Fuel allowance, Gallons, per 62 miles
1	61	1212	15.5	1.32
2	85	1873	19.8	1.58
3	122	2535	22.3	1.90
4	183	3086	24.8	2.19
5	275	3527	28	2.51
6	Above 275	3857	31	2.91

PATENT OFFICE BILL FAVORED

WASHINGTON, Feb. 18—The House this week accepted the conference report on the Nolan bill providing for increases in the force and salaries in the Patent Office and for other purposes. The section imposed by the Senate vesting authority with the Federal Trade Commission to accept assignment of patents made by government employees except employees of the Patent Office, was accepted by the conferees and the house. The commission will have power to administer government patents and the right to say who shall have commercial rights, where the inventor surrenders his patent and rights thereto to the government.

AUTHORIZE AIRCRAFT PAYMENTS

WASHINGTON, Feb. 19—Manufacturers of aircraft now engaged in fulfilling Government contracts entered into prior to June 30, 1920, will be paid provided the recommendations contained in the report of the House appropriations committee are approved. The fortification bill as reported out carried a provision authorizing the expenditure of $688,277.60, the sum requested by the Secretary of War. The majority of these contracts are only partly completed and the manufacturers advised the War Department that an extension was required.

Big Tractor Demand Foreseen in South

Diversification of Crops as Outlined Creates Wide Need for Power Equipment

ATLANTA, Feb. 19—That the widespread program of crop diversification that is to be followed in the South this year will serve to materially increase the demand for tractors and power farming machinery, and that the effect of this program will be lasting so far as the future development and prosperity of the power farming industry is concerned in the South, is the opinion expressed by the various branch managers of the manufacturers, most of whom maintain Southern headquarters in Atlanta.

There is little or no doubt but that the South will greatly reduce its cotton acreage this year. This abandoned acreage will be devoted to food and feed crops, and with thousands of Southern farms following this program a broad market is thus created for power machinery, principally tractors. Very few of those farmers who have been devoting their time to cotton for a number of years, and who will this year abandon most of their cotton acreage and diversify their crops, are equipped with modern power machinery.

Agricultural experts of the various State departments contend that diversification, to be practiced with any degree of real success, almost necessitates the use of modern power equipment on the farm, and especially the use of one or more tractors for plowing and cultivating purposes, and a host of other duties that this machine is capable of performing. Without such equipment, it is pointed out, the shortage of farm labor will serve to greatly reduce the agricultural production, as compared with production which could be obtained under the modern and scientific methods of power farming.

States Urge Motorization

For that reason the State agricultural departments of the various Southern States are endeavoring to convince as many farmers as possible that power farming will solve the problem of greater production, enable them to get back on their feet and enjoy their full share of the prosperity. The whole idea is to get as many Southern farmers as possible to using tractors and power machinery before the 1921 spring planting season is at hand.

In the opinion of distributors in Atlanta who cover the whole Southeastern field, right now is the time for the tractor and implement dealers to go after the business. A cotton acreage reduction of from 33-1/3 to 50 per cent is an assured fact, and as the farmer is fully aware that his production will be materially lessened unless he does operate his farm along more scientific lines, he is open for conviction. Experiences of some dealers the past few weeks, who are out after the business, has proven this to be a fact.

The Southern farmers have had this power farming idea drilled into them for the past three years until thousands of them are now "convinced." Power machinery is not so vitally important to cotton production, but it is vitally important to other crops, and the farmers who will practice diversification this year know it.

United States Tractor Adds $300,000 Capital

MENASHA, WIS., Feb. 18—The U. S. Tractor & Machinery Co., at its annual meeting decided to increase the capital stock from $500,000 to $800,000 to accommodate the development of the business. During the year the manufacturing area has been increased from 7500 to 25,000 sq. ft. All of the facilities have been in production steadily, and since Feb. 1, some departments are operating overtime, and night shifts are in prospect. Branches have been established at Kansas City, Minneapolis, Springfield, Ill., and New York City.

W. O. Otis has been appointed sales manager to fill the vacancy caused by the resignation of E. J. Perkins. The tractor line has been increased from one to three models, and the line of governor pulleys from one size to six. Officers were re-elected as follows: President, J. G. Sailer; first vice-president, Christian Walters; second vice-president, George J. Mayer; treasurer, Dr. A. B. Jensen; secretary and assistant treasurer, G. D. Harris; assistant secretary, G. E. Lewis.

TO MAKE TRACTOR IN MEMPHIS

MEMPHIS, TENN., Feb. 21—The Ideal Tractor-Cultivator Co., organized under the laws of Delaware with an authorized capital of $1,000,000 will manufacture a newly patented farm tractor at Memphis. The new firm will be located at the plant of the North Memphis Machine Works on the Belt line. The machine works will continue as before this line being added. J. P. Stanton will continue as manager of the plant. R. L. Tolston of Memphis is the inventor of the tractor. Officers of the company are Robert F. Carr, president of the Union Motor Car Co., president; vice-presidents, W. J. Meyer, Memphis; S. B. Street, Columbus, Miss.; R. F. Moorehouse, Springfield, Mo. R N. Phillips, of Memphis is secretary and treasurer.

STOUGHTON APPROACHES NORMAL

STOUGHTON, WIS., Feb. 21—As the result of orders taken at the various shows held so far this year, the motor truck division of the Stoughton Wagon Co., is increasing its force and probably will be employing a normal force by March 1. Other departments, which manufacture farm wagons, manure spreaders and similar equipment, are still running at a relatively small part of capacity, but new orders are being received in an encouraging volume.

Tractor Study Shows $4.21 Cost an Acre

Depreciation Shown High in New York State Analysis—Average Life Six Years

ITHACA, N. Y., Feb. 21—From studies of the cost of tractor operation made on eighty-seven New York State farms for the year 1919, the State College of Agriculture finds that the average cost of operation of a tractor without an operator was $1.16 an hour. The average cost of a tractor operator was 50 cents an hour and the average cost of the two-bottom plow was 36 cents an hour, making the average tractor cost operator and plow $2.02 an hour. The average rate of plowing on these farms was 4.8 acres in ten hours of work, making the average cost of tractor plowing $4.21 an acre. With present fuel prices, this cost would be slightly increased, and varies as fuel costs advance or decrease.

The average annual cost of tractor operation on these farms was $600 for tractor and operation. The largest single item of cost was depreciation, which amounted to $187.25, while the average life of the tractors amounted to six years. Other costs in order of importance were: Tractor operation, $166.63; fuel, $137.38; repairs, $44.25; interest, $39.72; chore and other work on tractor by farm labor, $38.94; lubricants, $37.58; other costs, $8.25.

The average number of hours worked by these tractors annually was 425, of which 321 hours were drawbar work and 104 hours belt work. This number of hours may be compared with the average number of hours worked by a horse on New York farms, about 900 to 1000 hours annually, or about three hours for each working day. The smaller number of hours worked by a tractor is due partly to the fact that the tractor completes the heavy work in a shorter space of time, and partly to the fact that it is less adaptable than horses. Many kinds of horse work cannot be done with advantage by the tractor, but most of the heavy work can. There is a growing tendency to apply the tractor to new tasks as operating experience increases.

Working Hour Range Wide

The number of hours worked by tractors on different farms ranged from 47 to 1277 for the year. Those farmers, who were able to keep their tractors busy at profitable work were able to reduce considerable the tractor cost. On nine farms on which tractors were used an average of 1001 hours each for the year, the average cost without the operator was 85 cents an hour, while on 31 farms on which tractors were worked an average of only 203 hours for the year, the average cost an hour was $1.72 for the tractor without the operator. Including the cost of operation and plow the respective hour cost would be $1.71 and $2.58, and the respective costs of plowing an acre $3.56 and $5.38.

Ford Predicts 70,000 March Output

Dismisses Stories of Financial Need

Now Employing 15,800 Men in Alternating Shifts—Car Surplus Nearly Liquidated

DETROIT, Feb. 23—In an interview to-day with a representative of AUTOMOTIVE INDUSTRIES, Henry Ford declared that 15,800 men now are working in the Highland Park plant. Production ranges around 2200 cars daily. Finished cars, together with engines and parts for the assembly branches, constitute the Highland Park output.

Ford said the company had 95,000 cars in the hands of dealers when the plant closed just before Christmas and 30,000 more under construction at branches. The 30,000 were finished in January while the Highland Park plant was closed. Retail sales aggregating 57,000 cars in January liquidated the 30,000 in the assembly branches and 27,000 of the 95,000 in the hands of dealers.

Retail sales the first half of February were 42,000 and total production 35,000. If this ratio of sales continues, approximately 50,000 of the surplus will have been liquidated this month. Ford said the March dealer requirements would be 70,000 and the plant would build 3100 daily in March.

Uninterrupted operation and increases in the working force, as well as an output in conformity with demand, will depend entirely on steel prices, Ford said. The River Rouge plant has not been closed at any time and approximately 1000 men have been employed there continuously. The force was increased today to 2600 manning the blast furnaces, building tractors, and doing other work. The production schedule for tractors now is 100 daily.

Ford dismissed questions regarding financing by saying, "The best indication of our position is the fact we are going to build 70,000 cars in March and we could not buy materials and meet payrolls without money."

Future of Industry Assured

Ford is highly optimistic and has full confidence in the future of the industry as well as its continued improvement. He said the rotating system of employment would be continued until the main factory is again in normal production. All men who are to be retained permanently will be given an opportunity to get part time work. No wage reductions on specific jobs will be made, Ford said, and there will be no reduction in the minimum wage.

E. C. Kanzler, brother-in-law of Edsel Ford, apparently is functioning at the Highland Park plant as production manager and Charles E. Sorensen as general manager. It is understood the policy of the company in future will be to abolish titles and that six or seven men will handle the work. They will specialize along certain lines but without titles.

NEWS BULLETINS

WASHINGTON, Feb. 24—Recommendations of the War Department for the disposal of surplus automobile equipment were adopted by the Senate committee on military affairs in reporting the army appropriation bill to the Senate to-day. The item, if passed without amendment, would to a large extent block efforts of Congressman Anthony of Kansas to dump army automobile equipment on the open market. The Senate bill specified that the total transfers and sales during the first six months of the present calendar year must not aggregate in excess of 10,000 motor trucks and 2000 passenger carrying automobiles.

The House bill, which carried the Anthony provision, required the sale and not transfer of motor vehicles. Brigadier General Lord told the Senators this week "the House committee put that word 'sell' in there with malice aforethought so that the money would go into the treasury" and Senator Lenroot, of Wisconsin, agreed with him. Under the proposed legislation now before the Senate all points of law are met because under existing law the War Department must give other Federal departments a choice of trucks.

NEW YORK, Feb. 24—A. B. Jones, formerly vice-president of the B. F. Goodrich Co., has been elected president of the Kelly-Springfield Tire Co. He will succeed F. A. Seaman who was acting temporarily as president. Seaman was elected a vice-president of the company.

CHICAGO, Feb. 24—The Stewart-Warner Speedometer Corp. has acquired the speedometer business and certain assets of the Van Sicklen Speedometer Co. of Elgin. The purchase did not include the capital stock which will retain its corporate entity. The Van Sicklen Co. is controlled by John N. Willys interests and has a new factory at Newark, N. J., which never was occupied.

NEW YORK, Feb. 24—An air mail plane which left San Francisco Tuesday arrived in New York yesterday afternoon. The mail was on the way only 33 hours and 20 minutes and the flying time was 25 hours and 53 minutes for the 2666 miles covered. The feat was made a success by a daring night flight from Cheyenne to Chicago through heavy storms. The flight was characterized as "a most momentous step in civic aviation."

Trucks Clear Snow in New York Storm

Motor Equipment Keeps Streets Open to Traffic in Season's First Test

NEW YORK, Feb. 23—Modern snow fighting equipment and a comprehensive plan of campaign enabled the Street Cleaning Department of New York to score a comparatively easy victory over the first heavy snow fall of the winter. The main arteries of traffic had been cleared by Monday night of the 13 in. which fell Saturday night and Sunday. More miles of streets had been cleared to-day than two weeks after the big storm last winter when the fall was not so deep. Four factors made the campaign a success. They were:

First—The equipment, consisting of 150 tractors, 350 trucks, over 600 push plows, about 150 four-wheel pull plows, 1800 department carts and about 850 contractors' vehicles which went to work very nearly on schedule time.

Second—The plan, begun last July, of training as many men as possible in four different schools in driving and handling this equipment made efficient work possible. By December these four schools had trained 649 men as drivers, so that all passed their licensing tests and became licensed chauffeurs.

Third—The entire city was divided into small zones, the equipment distributed in these zones, and every man assigned to his zone. At the same time each police station had a list of the snow fighting men living on the beats in that precinct, and the police were instructed to 'phone the police station the moment snow began to fall and get a list of these men.

Fourth—The street railway lines have about 3,000,000 sq. yd. of surface from which they were required to remove the snow altogether, not merely push it from the tracks. By agreement, the lines were given a full street, from houseline to houseline, approximating this area, which they were to clean entirely and which they did clean. In return, they were allowed to clear the tracks with sweepers and the city took care of the snow thus cleared.

Mishaps Prove Slight

There were only two hitches. Some of the push plows were installed on the heavy tractors without a bracing bar with which they were supposed to be fitted. As a result, five of these plows were put out of commission by the heavy tractors and one by one of the lighter tractors. The other mishap was on Sunday when gasoline supplies gave out for a time.

Goodyear Canvasses for Support of Plan

Officials Assigned to Visit Stockholders to Enlist Support in Financing Move

AKRON, Feb. 21—Many officials of the Goodyear Tire & Rubber Co. have been dispatched to all points of the compass to visit stockholders of the company and explain the proposed refinancing which will involve $85,000,000, so as to have enough favorable proxy votes of stockholders to insure ratification of the plan at the special stockholders' meeting called for March 4.

Stockholders' proxies are not coming as fast as had been anticipated, it is said. Officials of the company in sending notices to stockholders urged them to appreciate the necessity of extreme promptness in returning signed and voted proxies. The slow returns from these notices is said to have prompted the company in sending many of its men on the road, to visit stockholders and gain their signatures to proxies for the March 4 meeting.

Stockholders are asked to vote on several important matters vitally affected by the proposed refinancing, and upon the ratification of which it is said the definite consummation of negotiations hinges. Unless the plan is accepted by both stockholders and merchandise creditors it is recognized that the only alternative is a receivership.

It is admitted openly in Akron that the whole future of Goodyear depends upon approval of the financing plan by stockholders. The Goodyear company is so big, the ramifications of its interests are so far-reaching, and its place in the American industrial structure is so prominent, that anything looking to its failure would amount to nearly a calamity. Two months ago stockholders agreed to a plan of issuing $50,000,000 first mortgage bonds, but it having been found that other securities must be issued in order to completely satisfy the situation, additional consents must be secured to the new plans involving $85,000,000. The failure of Goodyear would amount to a business disaster which would be so far-reaching as to affect many other lines of industry.

Hesitate On Added Burden

It is also stated that stockholders having already approved the $50,000,000 refinancing plan, feel considerable hesitancy about giving new consent to added encumbrance of the company's property and inventories without first having it explained to them exactly why such additional financing is necessary.

Since the issuance of the annual statement of Oct. 31, 1920, the company's indebtedness, including contingent liabilities, has increased nearly $66,000,000, largely by reason of delivery of raw materials contracted for at high prices, and also by reason of further depreciation of materials delivered and covered by contracts for future deliveries. In December it was estimated that the company's deficit was $24,400,000, and that at the present time the additional estimated depreciation of materials contracted for but not yet delivered is $18,247,000.

The statement on present debt and capitalization shows a bank debt of $44,981,500. This includes $18,825,000 as a special secured loan negotiated last November, $13,594,000 including other obligations secured by rubber used in current operations, and $12,202,500 of unsecured notes and other commercial paper. Other secured notes payable are listed at $467,830, and bills receivable discounted by the company are listed at $1,970,000.

Merchandise Debt $11,305,104

The merchandise debt is listed at $11,305,104. Taxes will amount to $4,387,026, preferred stock subscriptions of employees to be refunded of $318,701, and miscellaneous indebtedness of $413,573. With other contingent estimated obligations of $2,120,556, the company's total indebtedness so listed is placed at $65,964,290.

Present commitments for future deliveries of merchandise on which specifications and prices have been fixed total $54,959,503. This sum includes $7,200,740 on rubber, $5,664,000 on cotton, $41,879,763 on fabric, and $215,000 on other materials. In addition the company estimates its depreciation of materials covered by commitments, not heretofore written off, of $18,247,000.

The approximate capitalization is $65,000,000 of 7 per cent preferred stock and $61,000,000 of common stock.

Bankers Extend Loan

NEW YORK, Feb. 23—The loan of $18,825,000 which was made to the Goodyear Tire & Rubber Co. several months ago by a banking syndicate headed by Goldman, Sachs & Co. and which matured Feb. 15, has been extended for 30 days with an option on a further extension of 60 days.

NEW CASTLE RECEIVER NAMED

NEW CASTLE, PA., Feb. 18—E. W. Beadel, local manufacturer, has been appointed receiver for the New Castle Rubber Co., in a meeting of creditors this week. The company failed during the recent financial reorganization of the Goodyear Tire & Rubber Co., although not an allied property. A quantity of Goodyear stock was listed as a large portion of its assets. F. A. Seiberling was not individually interested in the company, but it is understood that his son had a prominent part in the organization of it.

FILE NEW FORT WAYNE SUIT

FORT WAYNE, IND., Feb. 19—Another suit on account and for the appointment of a receiver has just been filed against the Fort Wayne Tire & Rubber Co. The complainant is the Quaker City Rubber Co. The demand in the complaint is $35,000, making a total of $136,000 demanded from the company in four suits.

Kalamazoo Plants Increase Operations

Fuller Finds Healthy Tone to Business—Barley Looks to Good Sales Year

(*Continued from page* 475)

since the shows in New York and Chicago" said Handley. "We have made numerous favorable distributing connections and look for a steady increase in our business. Our new car is well received wherever shown and I predict a ready market for all we can make this year."

Frank D. Fuller, president of Fuller & Sons Mfg. Co., reported that business is quiet, but enjoys a more healthy tone than anytime within the past three months.

"We are equipped to do a large volume of business" said Fuller. "That is shown by the fact that during the first nine months of 1920 we were able to produce three million dollars worth of truck transmissions. We are operating on part time schedule at this time, but are planning to steadily increase our working force."

The Barley Motor Car Co., makers of the "Roamer," enjoyed their best year during 1920 and are now preparing for a good run this season. It is expected to nearly equal the 1920 production. The car is meeting with added favor year by year.

The Dort body plant is now ready for a large production when the demands require it. The equipment throughout is high class and the two big structures have been laid out so as to provide the greatest efficiency in operation. A small force of men is now employed and Will Henderson, manager, believes that many more hands will be required in the near future.

While it is particularly quiet in the truck and tractor lines, both the Kalamazoo Motors Corp. and the Reed Foundry & Machine Co., makers respectively of the "Kalamazoo" truck and the "Reed" tractor, look forward to an early revival in trade.

TO EXTEND FORT WAYNE PLANT

FORT WAYNE, IND., Feb. 19—The General Electric Co. has purchased sixty acres of ground for the expansion of its local plant, which during normal business conditions employs about 6000 men. The local plant makes a large quantity of electrical equipment for automotive concerns.

WESTERBURG RECEIVER NAMED

NEW YORK, Feb. 23—J. N. Warren has been appointed temporary receiver for C. H. Westerburg & Co. of this city. He is serving without compensation in an attempt to bring about an agreement among the creditors which will forestall attempts to have the company declared bankrupt. The assets of the company virtually balance the liabilities.

Army Starts Sale of Surplus Cars

Anthony Bill Faces Probable Defeat in Senate—Legislation May Be Delayed

(*Continued from page* 474)

and 1000 automobiles. His move has been met with proposed bills requiring the transfer to the Bureau of Public Roads and subsequently the sale to State highway departments at a nominal sum.

It is understood here that Senators will block the Anthony amendment when the Army bill is called up, and substitute a proviso authorizing transfers. According to Senate leaders, there is a chance that President Wilson will veto the Army appropriation measure because it contains certain features objectionable to him. In that event, it would appear that the bill must go over until the extraordinary session of the Sixty-seventh Congress which will be called in March or early in April. The Army will have sold a large share of the equipment and the Anthony amendment rendered useless.

It is likely that the next sales of surplus equipment will be held at Camp Jessup near Atlanta, a concentration camp for the Motor Transport Corps; El Paso, and San Antonio, Texas for equipment held on the border, Jeffersonville, Ind., for equipment owned in the Middle West, San Francisco for machines held in the West. The Motor Transport Corps also has depots at Columbus, O., New Cumberland, Penn., Perth Amboy, N. J., Schenectady, N. Y., and Norfolk, Va. They have not yet determined where the next sale will be conducted.

It is customary to allow bidders to inspect the equipment for three days prior to sale and then bid according to auction lot numbers listed in the official catalogue. Inasmuch as machines are not ready for operating under their own power, the successful bidders are urged to make preparations for immediate removal as the liability is assumed immediately after the sale. The sales are conducted by professional auctioneers. Judging from the prices obtained at the Baltimore sale, the auctions throughout the country will net the Government several millions.

SEEK REPEAL OF PUMP RULING

MILWAUKEE, Feb. 21—An appeal by manufacturers of certain types of gasoline pump equipment from the ruling made a year ago by the Industrial Commission of Wisconsin, prohibiting the use of visible tank pumps, is under consideration. It is said there is small hope for a repeal of the order. Manufacturers of visible tanks claim it is to the best public interest that the visible type be permitted, so the consumer may be able to determine for himself if he is getting the amount of gasoline he pays for. The opposition, headed by Frank R. Daniel, chief inspector of the Wisconsin Fire Inspection Bureau, contends that the number of filling station fires has been increasing; that in other States serious fires and catastrophes occurred from the use of visible tanks and electrically driven pumps, and that there have been cases where the rays of the sun caused losses by ignition from the focusing of the rays through the glass tanks.

General Motors Assets Increase $156,100,479

NEW YORK, Feb. 21—Estimated consolidated balance sheet of the General Motors Corp. and subsidiaries as of Dec. 31, 1920, compares as follows:

ASSETS

	1920	1919
Real estate plant eq.	$248,000,000	$153,803,642
Misc. Inv.	63,000,000	53,398,491
Cash	49,278,000	48,231,200
Lib. bds., etc.	....	213,219
Sight drifts	11,000,000	....

Baltimore Buyers Pay $40 to $2400

(*Continued from page* 474)

John C. O'Brien, general manager of the Baltimore Automobile Trade Association, said the association's members protested to the Government because of the injustice of bringing machines from all over the country to be sold in this city. This, the dealers believe, would have a serious effect on future business here. They sought to have the Government sell the cars at the various Motor Transport Camps instead of bringing them to Baltimore.

FULLER REELECTS OFFICERS

KALAMAZOO, MICH., Feb. 21—Fuller & Sons Mfg. Co. report the result of their annual election as follows: President, Frank D. Fuller; vice-president, L. C. Fuller; secretary, Walter P. Fuller; treasurer, W. E. Upjohn. The above and S. N. Bickerstaff constitute the board of directors.

Metropolitan S. A .E. Visits Cooper Union

Laboratory Equipment and Testing Machines Discussed—Frame Design Merits Considered

NEW YORK, Feb. 18—The regular monthly meeting of the Metropolitan Section of the Society of Automotive Engineers was held last night in the Cooper Union Laboratories. Members of the section were given an opportunity to inspect the laboratory equipment, much of which was in operation. An automobile engine fitted with pressure indicating devices was run on the dynamometer stand. Two O'Kill pressure indicators were used to determine the maximum compression and explosion pressures and a Hospitalier manograph was arranged to project an indicator card on a screen provided for the purpose. The relative merits and utility of the two devices were later discussed.

In the strength of materials testing laboratory tension, torsion and fatigue testing machines were seen in operation, two of these being arranged to draw autographic records of the tests.

The paper of the evening was by Ethelbert Favery, who conducts the course in motor vehicle engineering at Cooper Institute. His talk dealt with a method of analyzing the stresses in automobile frames due to loading and road shocks, and included the development of a stress and shear diagram. The discussion which followed indicated that there is much interest in the matter of frame design.

Most of those who spoke appeared to favor rigid as against flexible or semi-flexible types. Three point suspension of the frame on the axles and of the engine in the frame, was favored by some speakers as tending to reduce distortion. One speaker stated that the tendency in passenger car design is toward deeper sections and stiffer construction in general.

Both the meeting and the dinner which preceded it were well attended.

COST MARK BILL OPPOSED

NEW YORK, Feb. 23—The Rubber Association of America has urged its members to oppose vigorously a bill introduced in the Minnesota legislature which would require the marking of merchandise with the manufacturer's cost, price at which it was sold to him, name and address of its distributor and the retail price of the article.

RESUME FORT WAYNE BUILDING

FORT WAYNE, IND., Feb. 19—The Greater Fort Wayne Development Co., which is putting up the homes to house the workers who will be employed at the new International Harvester plant here, is going right ahead with its work. It is expected that work on the Harvester plant will be resumed within a couple of months.

Decline Road Action Under Present Plan

Congress Asserts Highway Funds Now Being Wasted—Will Demand Results

WASHINGTON, Feb. 18—Efforts to force a continuation of Federal aid appropriations for highways by a rider on the Postoffice appropriation bill were defeated in the Senate to-day and assurances given that the proposed plan for a national system of highways as advocated by the automotive industry and organized automobile owners would be considered at the extraordinary session of the next Congress. Senator Thomas, Democrat, of Colorado, supported Senator Townsend, Republican, of Michigan, and chairman of the Senate committee on Postoffices and Roads, in opposing the amendment of Senator Swanson of Virginia. The Colorado Senator's threat to filibuster indefinitely against the proposed amendment served its purpose and the Senate rejected the Federal aid proposition.

Senator Swanson sought to persuade the Senate to accept his amendment which was the Federal aid bill passed in the House last week. He contended that 43 State legislatures would adjourn in March without knowing what the Federal Government was going to do in connection with road improvement. The Bureau of Roads data showing that on December 31, 1920, $149,683,107 was either under actual construction or completed leaving $117,066,893 on that date available for new contracts was submitted to the Senate.

During the debate on the amendment, Senator Townsend advised the Senate that the committee on postoffices and roads would undoubtedly report on the national highway system measure and other road measures now pending in committee. He expects that action will be taken by Congress before July 1. He pointed out that it was necessary to devise a scheme to get results for money spent on roads instead of wasting it under present method of distribution.

ARMY AIRCRAFT BILL OFFERED

WASHINGTON, Feb. 19—Senator New of Indiana has introduced a joint resolution which would authorize the Air Service of the Army to conduct extensive investigations as to the need of new designs in aircraft engines and other equipment used in aerial offense against seacraft. The legislation directs that obsolete warships should be turned over to determine the effects of missiles dropped from aircraft. Airplane builders expect that the tests will lead to more extensive use of bombers.

AEROMARINE TO OPEN SCHOOL

NEW YORK, Feb. 21—The Aeromarine Engineering & Sales Co. will open a training school for aviators this spring at Raritan Bay, Keyport, N. J., according to C. F. Redden, president of the company. It will be operated in connection with the sale of surplus navy flying boats recently taken over by the Aeromarine company. Students at the Aeromarine school will receive instruction in both land and water flying, giving particular attention to straight flying and navigation necessary in operating passenger carrying machines. They also will be taught practical airplane construction.

Price Guarantee Merits to Be Ruled on Singly

WASHINGTON, Feb. 18—Economic readjustment has forced the Federal Trade Commission to adopt an open attitude in regard to guarantees against price declines in business. It was announced this week that the Commission would consider the merits of the practice in specific cases rather than consider the subject in a general way.

The Commission finds that so many complaints have been received about the practice of manufacturers guaranteeing commodities in the hands of wholesalers against decline in price, that an inquiry showed the impossibility of dealing with the matter in its broad aspects. The Commission will consider the legality of each case and its effect on business.

Truck Limit Ruling Restrained by Court

YOUNGSTOWN, OHIO, Feb. 18—Scoring a partial victory against the Mahoning County commissioners in a fight to prevent restriction of heavy duty truck operations, attorneys for the Youngstown Automobile Dealers Association have obtained from the Appellate Court a temporary restraining order, preventing the commissioners from enforcing their bridge weight limitations. Judge Cooper in Common Pleas Court this week dissolved a temporary injunction which he had granted three weeks ago. In raising the bar, Judge Cooper issued a decision supporting the rights of the county commissioners to limit the bridge weight capacities, but based this ruling on his interpretation of statutes that this action could be taken only to safeguard life and property, and that such action could be effective only for a "reasonable time" in which to carry out repairs and reconstruction.

UNION RETAINS OFFICERS

BAY CITY, MICH., Feb. 18—No changes were made in the officers or directors of the Union Motor Truck Co., which met at its annual meeting a few days ago. During the past year earnings were such as to enable the company to pay charges and dividends on its preferred stock and to leave a surplus over all liabilities. The company bought more than $270,000 worth of materials from Bay City merchants and paid out more than $250,000 in wages. Production has been cut down, but there has been no complete shut down.

Little Car Claims Asserted Falsities

Six or Seven Cars Made All Different Is Testified—Blacksmith Made Parts

DALLAS, TEX., Feb. 19—Blacksmiths made a great many of the important parts of the first automobiles assembled at the plant of the Little Motor Car Co., according to testimony given in Federal Court here at the trial of W. S. Livezey, president of the concern, and other officers and promoters charged with using the mails to defraud.

The company was thrown into the hands of a receiver and the arrest of Livezey and others followed more than a year ago, after thousands of persons had subscribed to stock in it at $1 and $2 a share.

C. E. Peters, consulting engineer of Cleveland, who came to Dallas early in 1920 to superintend the assembling of the first cars, said he found many important parts had been made by a Dallas blacksmith. These included spring pads and spring clips, the steering wheel link and one of two brake drums. Of the two brake drums, he said, one was a Ford part and the other was a home-made affair, and neither was suitable for the brake design called for. The stability, workmanship and construction of the first cars, he said, were very crude.

"There were six or seven cars on the floor," he declared, "and no two of them were alike."

The officers of the concern, he said, took little interest in the work and never consulted him or advised with him. One of them, he said, put a wooden frame on one car and spent the rest of his time painting his own touring car which he had recently purchased.

In advertisements it was claimed that $1,000,000 worth of material was on the ground. This statement, employees have testified, was utterly false. Other claims in a letter to a prospective purchaser were that the company had so many orders it could not find time to answer mere inquiries.

FISHER UNIT NEAR COMPLETION

CLEVELAND, Feb. 21—The mammoth body building plant of the Fisher Ohio Co. is nearing completion and is expected to be in operation on March 1. The plant, which is one of the largest industrial units in the State and is said to be the last word in construction for automobile body building, is equipped to do a business of $20,000,000 a year. The Detroit company will provide the new company with that much business.

The Fisher corporation guarantees the 8 per cent dividend on the Fisher Co. from April, 1920, until July 1, 1922, the first payment of which was made Jan. 1. After that time it is expected that the Ohio company will be able to keep up its dividends on its preferred stock.

INDUSTRIAL NOTES

Stout Engineering Laboratories, Detroit, in which the new Stout batwing monoplane is being produced, are being moved this week to a large building on Beaubien Street. The factory now has $500,000 worth of orders booked, according to officials, and all of these are scheduled for delivery this year.

United States Motor Truck Co. has established a distribution connection in Kansas City. The new company is affiliated with the St. Louis sales company and the Marion County Motor Co. of Centralia, Ill.

American Motor Body Co., which owns the Wadsworth Mfg. Co. of Detroit, is now working 500 men on an old order for Ford Sedan bodies. It has employed 150 men in the finishing room since it reopened, Feb. 1. It normally employs 3500.

Miller Rubber Co. has removed its New York export branch to 121-125 Duane Street, where it will have larger office and storage facilities. The export headquarters will remain in Akron.

Van Briggle Officials Are Indicted for Fraud

INDIANAPOLIS, Feb. 21—Lilburn H. Van Briggle, president of the Van Briggle Motor Device Co., has been arrested on a charge of using the mails in a scheme to defraud, as a result of an indictment returned last Monday to Judge Anderson by the Federal grand jury. He was released on bond of $10,000 and will be arraigned in Federal Court March 7. Henry S. Rominger, treasurer, and Charles A. Taylor, sales manager, also were indicted and arrested on similar charges.

The defendants are charged with making false representations as to the financial condition of the company, which manufactures Van Briggle carbureters and shock absorbers for Ford automobiles, to prospective purchasers of the capital stock of the company. Van Briggle is accused of having purchased large blocks of stock in his company and then selling it to third parties at a high price, representing that it was treasury stock. It is also alleged that he failed to pay for the stock so taken by him.

Charge Fraud in Sale of Victor Truck Stock

BENTON HARBOR, MICH., Feb. 19—E. E. Edgar and John S. Watt of Harvey, Ill., have filed suit alleging misrepresentation and fraud against the Victor Truck Co. of St. Joseph, Mich. The suit is said to be the outcome of the failure of the Baroda Commercial Bank a short time ago. One of the principal defendants is A. E. Rick, president of the defunct bank, from whom a full accounting is asked by the plaintiffs.

The petition asks the appointment of a receiver and a full accounting from F. D. Allis and C. C. Van Wagoner, officials of the truck company.

The petition recites that Van Wagoner by dubious methods induced the plaintiffs to invest heavily in stock in the company. Edgar and Watt, according to the petition, were to be distributors in Wisconsin, Illinois and Minnesota, and they allege they deposited $500 for parts and supplies and bought two trucks for $3,200 on the statement of Van Wagoner that the St. Joseph Co. was financially sound and producing trucks in marketable quantities. These statements, the plaintiffs allege, were untrue.

Petitioners also allege Van Wagoner approached them in January of this year and persuaded them to buy 200 shares or two-thirds of the common stock of the company owned by G. A. Fitch of St. Joseph for $10,000. Half of the money was paid in cash January 8 and a 60-day note was given.

Kelly-Springfield Tire Shows $7,721,901 Profit

NEW YORK, N. Y., Feb. 23—Gross profits of $7,721,901 the second largest in the history of the company, are shown in the annual report of the Kelly-Springfield Tire Co. for 1920. Net profits were $3,430,914, also the second largest ever reported, although unusually large deductions were made leaving a balance of only $1,959,293 before providing for taxes, compared with $2,853,571 for 1919. The deductions in 1920 amounted to $2,076,152 which included $500,000 for fluctuations in inventory valuations as well as for losses on Liberty bonds and deduction of fixed and miscellaneous charges.

After payment of preferred dividends but before allowance for taxes, the amount available for common stock was $1,296,255 or approximately $4 a share on $8,061,000 worth of common stock outstanding Dec. 31 as compared with 50 per cent on $5,361,978 common in 1919.

President Frederick A. Seaman stated that the company had no supplies or contracts for raw materials at former high prices and is in a position to take advantage of low levels for future requirements. The first nine months of 1920 showed marked improvement over the same period in 1919 but there was a marked falling off in business for the last quarter. Completion of the new plant at Cumberland, Md., has been delayed but it is expected to be opened during March.

FORD PATENT SUIT FILED

BOSTON, Feb. 18—A bill in equity was filed in the Federal District Court here by William B. Moses of Watertown against the Ford Motor Car Co. of Detroit, and Laline & Partridge, Inc., 1255 Boylston Street, charging an infringement of patent rights in certain improvements in starting, generating and lighting apparatus, and seeks temporary and permanent injunction restraining the joint defendants from causing to be made or sold or offered for sale Ford motor cars containing an infringement on his invention.

METAL MARKETS

THE nearer we come to the end of the padding that war inflation has wrapped around iron and steel prices the more obvious becomes the irremovable character of that part of the swollen levels which is due to high freight rates. It costs to-day upward of $10 for freight to assemble the iron ore, limestone, fuel, etc., necessary to produce a ton of pig iron. In 1897 and 1898 pig iron sold for less money per ton to the consumer than it costs the blast furnace in freight to-day for the raw material to produce a ton. Until the Interstate Commerce Commission applies the pruning knife to freight rates, there is no possibility of a recession to pre-war prices, even though every other cost ingredient may have been pared to what it was before the war. With reports current that a round tonnage said to approximate 25,000 tons has been taken off the market by speculative interests at a price below $25 for basic, the question presents itself whether the pig iron market can go any lower considering that, deducting the $10 freight on raw material, the blast furnace that sold this tonnage will receive less than $15 for raw material, labor and overhead. Noteworthy also is the character of this transaction, the buyers being speculators who will hold the iron for an advance and the sellers steel producers who do not need it because of the idleness of most of their steel making capacity. In other words, large financial interests believe that, until freight rates are reduced, the pig iron market can not go lower. From the point of view of the automotive foundry buyer, the differentials quoted on foundry and malleable over basic prices are still somewhat askew. To understand clearly the situation in the steel market which newspaper reporters seek to exploit in the only way such material can be turned into "first page stuff," i. e., a battle royal between the Corporation and the Independents, it must be borne in mind that the Corporation, in the very nature of its organism, can not alter its price and operating policies as frequently and swiftly as the smaller interests. It is now shipping steel at somewhat higher prices than those quoted in the open, "independent" market to many consumers to whom it sold much more steel at the same prices last year, while the "independents" were then asking considerably higher levels.

Pig Iron—Middle West automotive foundries have been bidding $26 @ $27 for foundry and malleable, valley basis, producers being apparently disposed to consider negotiations with such bids as a basis and countering with offers of $1 to $2 higher. The situation has narrowed down to a case of haggling over price in each individual transaction.

Steel—Somewhat better inquiry is noted for cold-rolled strip steel from automotive sources. Cold-finished steel bars are sought at concessions which many makers are unable to grant because they depend for their hot bars on the Corporation. Pittsburgh reports state that the Ford Motor Co. and other Detroit passenger car builders are issuing more shipping instructions for sheets.

Aluminum—While some odd lots of foreign 98 to 99 per cent metal are offered at 24c., the general "outside" quotation is 25c., with demand light.

Lead—The chief interest has reduced its official quotation to 4.50c., New York and East St. Louis. The "outside" market is 4.25c., East St. Louis.

FINANCIAL NOTES

Savage Arms Co. reports total earnings for 1920 as $117,000, equal to $1.35 a share on the $7,748,000 of common capital stock outstanding. In 1919 the company earned $2,032,000, which was equal to $19.28 a share. After the payment of common dividends, including the extra payments declared during the year, the deficit for 1920 amounted to $631,000. In 1919 a surplus of $643,000 was reported.

Saxon Motor Car Corp. shows a gain in assets as of Dec. 31 over April 1, 1920, of $484,675. This is represented principally in inventories which increased from $747,493 to $1,770,036, and deferred charges, and machinery, trucks and equipment. Cash decreased from $1,091,151 to $62,561. A decrease in surplus is shown from $4,402,816 to $4,286,700.

Curran Motor Products Co., Detroit, has been organized with a capital of $100,000 to market automobile accessories, chiefly the inventions of Dr. E. T. Curran. Dr. Curran is president; W. N. Nahikian, vice-president; P. M. MacKay, secretary-treasurer, and P. T. Quinn, sales manager.

Dunlop's Ltd. the British tire company which is the parent of the Dunlop American company, proposes to issue debentures amounting to 3,000,000 pounds Sterling at 98 with interest at 8 per cent.. They will run for 20 years with annual drawings for retirement at 105.

Curtiss Aeroplane & Motor Corp. reports a net loss for 1920 of $1,756,582, which includes full depreciation on plant, securities owned, patents receivable and inventories, as well as cost of cancellation of contracts for material. It is declared no new financing is necessary.

Davis Steam Motors, Inc., Detroit, with a capital of $100,000 in shares of $10 par value, has been organized to market a steam engine for use in both passenger cars and trucks. The incorporators are Merrill Davis, E. M. Bliss, F. D. Siebert and A. B. Eggert.

American Bosch-Magneto Co. has reduced disbursements on its capital stock from $2.50 to $1.25 a share. This places the stock on a $5 annual dividend basis as compared with the previous rate of $10.

L. V. Fletcher & Co., New York, manufacturers of carbureters, has filed a petition in bankruptcy, with liabilties of $39,968 and assets of $14,369.

Ajax Rubber Reports $177,920 Loss in Year

NEW YORK, Feb. 21—The report of the Ajax Rubber Co. for the year ended Dec. 31 last, shows a loss of $177,920 after depreciation charges. This compares with a net profit of $2,201,267 for 1919. The balance sheet shows inventories of $7,408,968; notes and accounts receivable of $3,959,947; cash, $301,990, and deferred charges of $336,205. The total assets are $18,376,854. The liabilities include $6,145,000 in notes payable, and $528,292 in accounts payable.

Horace DeLisser, chairman of the board, says in a report to stockholders that the company is in a favorable position because of the comparatively small and evenly balanced inventory as well as because of the small amount of commitments placed for future deliveries of raw materials. At the end of the fiscal year this amounted to only $220,000 for rubber and $1,767,000 for fabric. De Lisser adds that in practically the first year of the company's efforts toward an export business, there were shipments of more than 1,100,000 Ajax tires and tubes to 60 foreign countries.

Apex Seeks Extension; Reorganization Planned

YPSILANTI, MICH., Feb. 23—Creditors of the Apex Motor Corp. have been asked to grant an extension of time for approximately a year to permit thorough reorganization of the company on a basis of reduced overhead and economical operation. The directors have accepted the resignation of O. W. Heinz as president and general manager and elected H. T. Hanover in his place. George P. Listman of Seattle has been elected a director.

A statement sent out by the company states that its financial condition was serious at the time the change of management was made, but that the United Finance Co., the largest creditor, with a claim of approximately $500,000, has agreed to an extension of 30 days to learn the views of other creditors and prepare a financial statement. If the other creditors will agree to an extension, the finance company will advance sufficient funds to get back into production to fill the orders on hand. The agreement with the finance company provides that all future business must be on a C. O. D. basis.

The directors have repudiated a refinancing arrangement entered into by Heinz with C. B. Haffenberg. This arrangement would have provided for the sale of stock and the directors would not permit this action in view of the company's financial condition.

Federal Truck Report Shows $806,812 Surplus

DETROIT, Feb. 17—Federal Motor Truck Co. reports total sales of $10,628,742.09 and profits of $745,878.66 for the year ended Dec. 31. Liabilities aggregating $4,525,340.50 include:

Notes and Accounts Payable	$ 352,734.39
Dealers' Deposits	31,843.93
Land Contract	335,360.00
U. S. Government Claim	359,091.87
Reserves for Depreciation, etc.	577,649.72
Capital Stock	2,000,000.00
Surplus	806,812.76
Assets include:	
Cash	$ 163,293.11
Notes Receivable and Acceptances	68,040.11
Accounts Receivable	160,770.88
Securities	192,505.26
Plant Accounts	1,383,248.90
Merchandise Inventory	2,497,398.25
Prepaid Expense	60,083.99

AJAX SEEKS PLANT SITE

BOSTON, Feb. 21—The plant location of the Ajax Motors Corp., Boston's only motor vehicle builder, has not yet been definitely determined. Pending the construction of its own plant, its products are being assembled at the Tracy plant in Rutherford, N. J.

Bank Credits

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, Feb. 24—The local loan market again eased toward the latter part of the week. Call money ruled at 7 per cent with a range of 6 per cent to 7 per cent as against a range of 7 per cent to 8 per cent the week before. A feature of the week was the reappearance of an "outside" market, where call money could be had at 6 per cent. There was little trading in time money, the supply of which was light until the latter part of the week. Sixty and ninety day paper was quoted at 6½ per cent to 7 per cent, and the longer maturities at 6½ to 6¾ per cent. Corresponding rates for the previous week had been 7 per cent and 7¾ per cent respectively.

Although the excess reserves of the New York Associated Banks declined $7,625,180, the loans and deposits continued to decline. Loans at $5,001,150,000 marked a decline of $20,216,000 from the previous week. Net time deposits declined $11,725,000 and net demand deposits decreased nominally.

The week-end statement of the New York Federal Reserve Bank showed a greatly improved reserve position for the local Bank. Gold reserves increased $25,499,000. Total bills on hand decreased $40,966,000 and total earning assets declined $43,266,000. Net deposits declined $21,101,000. The ratio of total reserves to Federal Reserve note and net deposit liabilities combined, increased from 39.4 per cent to 41.7 per cent. This ratio is higher than that for any week since last September.

The Federal Reserve Banks as a whole showed the same marked improvement as the New York bank. Gold reserves increased $10,674,000 while Federal Reserve notes in circulation declined $12,972,000. Federal Reserve Bank Notes declined $4,747,000. The ratio of gold reserves to Federal Reserve notes in circulation after setting aside 33 per cent against net deposits, increased from 57.6 per cent to 58.5 per cent. Bills discounted and secured by Government war obligations were down $21,495,000 and total bills on hand $50,107,000. Total earning assets decreased $51,923,000 and net deposits $25,535,000.

The stock market last week was dull and irregular with net gains, however, practically offsetting the losses. The bond market was also very quiet and was marked by fewer new issues than have been characteristic of recent weeks.

STORM KING EXTENDS PLANT

HARTFORD, WIS., Feb. 19 — The Storm King Mfg. Co. of Hartford, Wis., manufacturer of patented curtains for Ford and other cars for cold weather equipment, has been obliged to take over larger quarters to accommodate the expansion of its business and provide more adequate facilities. As rapidly as possible the output is being increased to 500 sets of curtains per month.

Men of the Industry

E. P. Chalfant, one of the veterans of the motor vehicle industry, has voluntarily taken an indefinite leave of absence from Automotive Products Corp. of New York, an export house which he organized two and a half years ago as an ally of the American Steel Export Co. He is also president of the Gill Mfg. Co., Chicago, and president of the Gill Piston Ring Corp., New York, and will hereafter devote himself actively to the affairs of these two companies, making his headquarters at the New York branch, 1864 Broadway.

A. D. Williams has assumed charge of sales for "X" Laboratories, manufacturers of "X" Liquid, and will be located with headquarters at their New York office. Williams formerly was associated with the American Chain Co., Bridgeport, Conn.; the F. Hersh Hardware Co., Allentown, Pa., and the last few years has been field manager for the Bethlehem Spark Plug Corp.

E. E. Westman, for the past two and one-half years director of purchases of the Premier Motor Corp. of Indianapolis and for many years connected with various automobile concerns of that city, has severed his connection with Premier to become secretary and treasurer in charge of sales for the Kant Kut Tube Products Co., Indianapolis.

Fred Rufenacht has purchased the plant of the Bucyrus Rubber Co., New Philadelphia, Ohio, and it is thought he will organize a company to operate it as the Crawford Tire & Rubber Co. Rufenacht is a coal operator of New Philadelphia and was an officer and stockholder of the Bucyrus company. Philip H. Heater has been appointed manager.

W. G. Thompson has been elected president of the Thomart Motor Co. of Akron and Kent, Ohio. The company was organized last April and started limited production in December of 1-ton speed trucks. James L. Stewart has been elected vice president and general manager, and B. A. Shriber, secretary and treasurer.

Jack Neely, assistant sales manager of the Barley Motor Car Co. for several years, has resigned his position and will be associated with the Studebaker Motor Car Co. He will be assigned to one of the numerous factory branches of the latter company, assuming his new duties as a branch manager about April 1.

R. S. Jemison, who has been connected with the advertising department of the Miller Rubber Co., has been appointed advertising manager of the Oldfield Tire Co., and has moved his headquarters from Cleveland to Akron. Jemison is widely known throughout the south as a writer on sporting topics.

Joseph E. Burns has succeeded R. G. Ewell as sales and advertising manager of the Allen Motor Co., Columbus. He was formerly territorial representative for the company and previous to that had been connected with the educational bureau of the Cole Motor Car Co.

F. S. Warren, for the last five years sales manager of the Booth Felt Co., Inc., New York, and previous to that for two years New York representative of the Advance Felt & Cutting Co., Chicago, has gone into business for himself in New York.

C. R. Miller has resigned as general manager of the Allen Motor Co., Columbus. He was formerly works manager at Willys-Overland and general manager of Miami Cyclex & Mfg. Co. His plans for the future are not announced.

Fred Wellman, for two years advertising manager of the National Motor Car & Vehicle Corp., has resigned his position to join the National Motor Sales Co. of Chicago, distributors of National cars, in the capacity of sales manager.

Ewart C. Hugh, formerly European traveling representative of the All American Truck Co., Chicago, has formed the Hugh Co., Buffalo, which will manufacture metal products for the automotive industry.

G. R. Harris has resigned as secretary-treasurer of the Troy Wagon Works Co., Troy, Ohio. W. J. Murray has been appointed general manager and H. H. Tamplin new secretary-treasurer.

Victor Greiff, E. E., who joined the American Bosch Magneto Corp. a year ago to install a research laboratory, has completed the work and returned to his home in New York City.

George J. Blanton, who for the past four years has been connected with the engineering sales department of Chain Belt Co., Milwaukee, has been made New York district manager.

Stephen A. Douglas has been appointed general sales manager of the William R. Johnston Mfg. Co., Chicago, manufacturers of automobile equipment.

Frank B. Willis has been appointed sales manager of the Duplex Truck Co., Lansing. He was formerly sales manager of the Kelly-Springfield Truck Co.

W. T. Norton, Jr., chief engineer of the Motor Transport, has resigned, and at the present time has made no definite connections.

Frederick T. Frazer has been elected a member of the board of directors of the Byron G. Moon Co., Inc.

Water A. Wood has been elected president of the New York Automobile Dealers Ass'n.

HARTMAN TO LEAVE FORD

DETROIT, Feb. 21—Hubert E. Hartman, assistant secretary and general attorney for the Ford Motor Co., has announced his resignation, effective March 15. He gave as his reason a desire to enter business for himself, adding that he expected to continue to handle some of the company's affairs. Hartman has been with Ford seven years.

HANDLEY RE-ELECTED PRESIDENT

KALAMAZOO, MICH., Feb. 21—The annual meeting of the Handley-Knight company resulted in the election of the following officers and directors: President and General Manager, James I. Handley; vice-presidents, W. E. Upjohn and C. S. Campbell; secretary-treasurer, Walter L. Otis; directors, the above and C. A. Blaney, Kalamazoo; J. S. Woodward, Battle Creek, and Walter Stewart and Martin V. Kelley, Toledo.

STANDARD AERO BANKRUPT

PHILADELPHIA, Feb. 21 — The United States Circuit Court of Appeals has affirmed an order of the District Court of New Jersey declaring the Standard Aero Corp. of New York a bankrupt. The proceedings were on petition of Charles H. Leonard of Elizabeth, N. J., a creditor. The plant of the corporation at Plainfield is located on ground leased from Leonard, who sued in the New Jersey court and obtained a judgment for $9,000.

The Aero corporation built airplanes for the United States and received payments of approximately $5,000,000. Its business ended with the armistice and its relations with the Government were ended by the further payment of about $1,000,000. This sum was disbursed and nothing was left except a bank balance of less than $400.

Wilson Appointment Rests With Chrysler

NEW YORK, Feb. 23—When asked today whether or not he had been invited to accept the general management of the Maxwell-Chalmers combination, W. R. Wilson, who is one of the vice-presidents of the Irving National Bank of this city, referred inquiries to Walter P. Chrysler, chairman of the management committee, which will make the appointment. He intimated the subject had been taken up with him, but added that he could not say whether the appointment would come to him. Chrysler has declined to make any statement.

Wilson, who is about 35 years old, is better known as a financier than as a production man, although he has had considerable experience in the automotive industry. He was associated with the Studebaker Corp. until the formation of the Dodge Bros. Motor Car Co. He assisted the Dodge brothers in perfecting their organization and remained with them five years in a confidential capacity.

DETROIT S. A. E. TO MEET

DETROIT, Feb. 21—The Detroit Section of the Society of Automotive Engineers will hold its February meeting Feb. 25 at the Detroit Board of Commerce. O. C. Barry, research engineer of the Hupp Motor Car Co., and formerly professor of automotive engineering at Purdue University, will speak on the fuel problem in terms of miles per gallon.

PATENTEE SUES G. M. C.

BOSTON, Feb. 18—Rollin Abell of Milton, Mass., has entered suit in the Suffolk Superior Court for $600,000 against the General Motors Corp. of New York for alleged repudiation by the defendant of an agreement to use a valve mechanism in connection with automobile engines, for which the plaintiff was to be paid not less than $50,000 a year.

N. A. C. C. MEETING MARCH 3

NEW YORK, Feb. 21—A general meeting of the members of the National Automobile Chamber of Commerce will be held Thursday, March 3. The passenger car manufacturers will meet in the morning and the truck manufacturers in the afternoon. The directors of the Chamber will meet Wednesday morning, March 2, and the truck committee that afternoon.

Calendar

SHOWS

Feb. 26-Mar. 5—Buffalo, Annual Automobile Show, Buffalo Automobile Dealers Ass'n, 74th Regiment Armory, C. C. Proctor, Mgr.

Mar. 2-10—Des Moines, Annual Automobile Show, Coliseum, C. G. Van Vliet, Mgr.

Mar. 5-12—Atlanta, Annual Automobile Show, Atlanta Automobile Dealers' Ass'n, Auditorium, Virgil Shepard, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 5-12—Pittsburgh, Annual Automobile Show, Automotive Ass'n, Inc., Motor Square Garden, J. J. Bell, Mgr.

Mar. 5-12—Atlantic City, Annual Automobile Show, Automobile Trade Association of Atlantic City, Million Dollar Pier, A. H. Generatzky, Mgr.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 7-12—Nashville, Annual Automobile Show, Nashville Automobile Trade Ass'n, Page Bldg.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

Mar. 14-19—Washington, Annual Automobile Show, Washington Automobile Dealers' Ass'n, Rudolph Jose, Chmn.

Mar. 19-26—Detroit, Annual Automobile Show, Detroit Automobile Dealers' Ass'n, Morgan-Wright Building.

April 3-9—Denver, Annual Automobile Show, Auditorium.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April—Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections.

April, 1921—Sofia, Bulgaria, Tractor Trials, under the Bulgarian Ministry of Agriculture.

May 28-June 8—International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

CONVENTIONS

May 4-7—Cleveland, National Foreign Trade Council.

Oct. 12-14, 1921—Chicago, Twenty-Eighth Annual, Convention National Implement & Vehicle Ass'n.

RACES

July 24—Grand Prix, Le Mans.

S. A. E. MEETINGS

Boston section—March 18.

Buffalo section—April 19—Paper on "Carbureter Performance," by F. C. Mock.

Dayton section—May 3.

Detroit section—March 25—Discussion of "The Relation Between the Industry and the Department of Engineering Research of the University of Michigan," by Prof. E. A. White.

Metropolitan section—March 10—Paper on "Brakes," by H. G. Farwell.

Metropolitan section—April 14—Paper on "Low Grade Fuel Carburetion," by A. H. Beach.

Midwest section—March 11—Discussion of storage batteries.

Minneapolis section—March 2—Discussion of good roads and equipment.

Minneapolis section—April 6—Discussion of repair equipment.

Washington section—March 18—Highway and Highway Transport Trading.

Washington section—April 1—Aeronautical Engineering Session.

Mexico to Construct Main Roads System

NEW YORK, Feb. 19—Approximately 22,000 kilometers of highways are included in the road improvement project of the Mexican government. This statement is made in a letter just received here from Salvador Medina, executive official of the Mexican Department of Roads and Public Works. Under the project the road work will be administered through regional groups, each of which will have a technical administrative center. Senor Medina describes the project as follows:

"This bureau has decided upon a project for the improvement of the leading roads of the Republic—a project covering the upkeep of all public roads during the present year, there also existing the plan of carrying out this work in all the States of the Republic, in accordance with a technical outline already approved. In the said project, roads are enumerated according to regional groups, which in due time will constitute actual zones of permanent attention, each one having a technical-administrative center.

"The center of each zone shall be Mexico City, Tampico, Queretaro, Guadalajara, Morelia, Iguala, Oaxaca, Tuxtla Gutierrez, Campeche, San Luis Potosi, Zacatecas, Chihuahua, Hermosillo, Ensenada and La Paz. The total extension of the roads covered by these zones is 22,000 kilometers."

LOWERS RATE ON STEEL PARTS

WASHINGTON, Feb. 18—An order was issued by the Interstate Commerce Commission this week requiring carriers to establish a rate of $1.125 on the pressed steel side members of truck frames, no higher than rates on structural steel channels. The order followed a decision by the commission in the case brought by the Moreland Motor Truck Co. against the C. M. & St. P. Railroad, in which it was found that the rate of $2.2115 per cwt. on pressed steel side members of truck frames, in carloads from Milwaukee to Los Angeles, was unreasonable.

Maxwell Contract Suit Moved to U. S. Court

TOLEDO, Feb. 19—The suit in which the Toledo Bridge & Crane Co. asks for a judgment of $34,901.79 from the Maxwell Motor Co., alleged to be due for breach of contract, was remanded from the common pleas court of Lucas county to the Federal court for the Northern District of Ohio, Western Division.

The Toledo company alleges that it had a contract for 40,000 oil pans at $2.50 each and that the contract was cancelled before completed.

The case brought a legal battle in the common pleas court but will be settled in the district court which is at the present time heavily loaded with business. The case will probably not be heard for several weeks.

CARRPLANE COMPANY FORMED

ATLANTA, Feb. 19—The first airplane manufacturing company in the South is to be located at Jellico, Tenn., the Southern Carrplane Mfg. Co., having been organized there with $250,000 capital. The plane to be manufactured will be known as the Carrplane. It was designed by Capt. Walter J. Carr, formerly an army aviator. L. E. Woody is president and general manager of the company; W. I. Jones is secretary and treasurer.

Safety Regulations Reduce Car Accidents

NEW YORK, Feb. 18—More playgrounds, more safety education in the schools, uniform traffic rules, and regulations against overloading are among the measures which the National Automobile Chamber of Commerce will advocate with increased vigor during the coming year as part of its program to reduce the number of accidents incidental to the operation of motor vehicles. In urging these causes, the chamber plans to assist organizations already active along these lines rather than to stimulate independent campaigns.

Official figures show a decline in the ratio of fatalities to the number of cars in operation. Automobile deaths per car were 0.0025 in 1914, and these were reduced to 0.0013 in 1919.

ALABAMA AIR CLUB FORMED

ATLANTA, Feb. 19—The Alabama Aeronautical Society, affiliated with the Aero Club of America, has been organized at Birmingham, Ala. Lieut. Commander C. W. Tindal, formerly of the United States Navy, was the organizer. It will be conducted along the same lines as the New York State Flying Club and the Missouri Aeronautical Society.

TO STAGE FAIR IN JAVA

NEW YORK, Feb. 19—An automobile and tractor exhibition will be held at Bandoeng, Java, Sept. 19 to Oct. 9, 1921, in connection with the Second Netherlands East Indies Fair, which will be international in character and which offers to manufacturers an opportunity for exhibiting their products in the highly lucrative markets of the East Indies.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV NEW YORK—THURSDAY, MARCH 3, 1921 No. 9

Plan to Center Automotive Research in S. A. E. Committee

New activity will be initiated and directed by this committee and carried forward by a research department organized as a part of Society's office staff. Important to collect and publish existing data.

By Herbert Chase

PLANS for putting into effect the research activities which it was recently announced that the Society of Automotive Engineers Research Committee had been authorized by the Council to undertake are developing and bid fair to assume the importance predicted for them. It has naturally proved impossible as yet to formulate details of the new activity, but it is understood that the work will be handled in much the same way that the S. A. E. Standard Committee work is handled. There will be an office organization with a Research Manager whose duties will include the collection of data and its preparation for publication. One of the Research Manager's duties will be to learn the view of the Research Committee, and where decisions are made to see that they are put into effect and followed through to a conclusion.

It is not proposed that the Research Committee as a whole, or such divisions thereof as shall be formed, will undertake the actual conduct of research, or finance its conduct in selected laboratories, but rather that it will arrange for such research as may be considered desirable, through co-operation with industrial laboratories as well as with laboratories of government bureaus, universities, etc.

Every effort will be made to correlate the work of various laboratories to prevent unnecessary duplication and to so arrange the work undertaken as to bring about solution of the most pressing problems of the automotive industry. The S. A. E. will thus act as a sort of clearing house for research work. It is expected also that much existing research data will be accumulated for reference and comparison, in fact, some members of the committee regard the collection and dissemination of existing data as the first and most important activity of the committee.

It is not to be expected, of course, that any one manufacturer's problems will be investigated by the committee, except in so far as such investigation will be of general benefit, but whenever the results of individual researches are made available to the committee these will in turn be made available to others in the industry who may be interested.

The committee as at present constituted is as follows: Henry M. Crane, Chairman. Harry L. Horning, E. A. Johnston, C. F. Kettering, J. G. Vincent, Herbert W. Alden, Dr. H. C. Dickinson, T. C. Menges, Joseph Van Blerck and Prof. O. C. Berry.

This committee will be added to from time to time as need requires and will no doubt be segregated into divisions, as is the case with the Standards Committee, should this prove desirable.

There are quite natural differences in viewpoint among members of the committee as to ways in

which the work to be undertaken can be made most useful, as to how it can best be carried forward and as to what subjects are of greatest importance. It is quite generally agreed, however, that research pertaining to fuel and its utilization is of paramount and most general importance.

One member of the committee takes the view that research gathered by the committee should be confined to very definite commercial ends—to the solution of problems of immediate and pressing importance to the industry. But the same member fully recognizes the need for digesting and publishing information now available. He indicated that some large industrial laboratories have already expressed willingness to co-operate with the committee, not only in making available information now in hand or in progress of collection, but by prosecuting for the general good of the industry lines of research laid down by the committee.

In some instances, more especially in the case of university students research where the investigators are frequently lacking in experience, it will doubtless prove desirable to have the same line of work undertaken in two or more laboratories in order that a check may be had.

One member of the committee is drafting for discussion a set of rules of procedure to govern activities of the committee. When patents are involved it will, of course, be necessary to proceed with caution in order not to favor any commercial interest. This matter will require careful handling.

It has been pointed out, quite properly, that a close relationship necessarily exists between standardization and research work. It is frequently necessary to carry through certain research work before a satisfactory standard can be formulated.

Coker F. Clarkson, General Manager of the S. A. E., believes that the decision to undertake the work with which the Research Committee is charged is of as great significance and importance to the Society as was the decision, arrived at many years ago, to undertake standardization work. The latter work required the establishment of a standards department in the S. A. E. staff and it is expected that a similar department will be built up to handle the detail prosecution of the research program. The Research Committee will formulate policies and lay out the program of work to be undertaken, but will necessarily have to depend largely upon the Research Department to carry the work forward. It has been agreed that the Society shall, at least for the first year, undertake work on its own resources, that is without seeking outside funds for the purpose. It seems quite likely, however, that as the work progresses and becomes of greater value to the automotive industry as a whole, the industry will participate in supporting it financially as it has the standardization work of the Society.

Some members of the committee feel that the automotive industry in common with most other industries, lacks appreciation of the value and importance of research fundamentals, and would confine the work of the committee to the determination of facts without attempting to apply the results of research to automotive products. The same persons lay stress upon the educational value of the work, believing that a better knowledge of fundamentals will result in more intelligent application of these fundamentals to the solution of the problems of the industry. If the committee can succeed in demonstrating to all concerned the need of more careful and thoroughgoing research, its hope that the quality of work turned out, especially by industrial laboratories, will reach a higher standard will no doubt be realized.

If various industrial laboratories agree, as is expected, to exchange information through the offices of the committee, it is evident that much duplication will be avoided, and a great deal gained both in time and cash outlay. Even if the committee succeeds in the first year in simply persuading industrial organizations of the advantages to all concerned of releasing data accumulated as a result of research conducted by these organizations its efforts will be well spent. In many cases standards of comparison are lacking, so that results obtained in various laboratories are not comparable. Efforts to bring about the general acceptance of such standards will enable ready comparisons to the benefit of all concerned, hence there is opportunity for fruitful results in work to this end.

There are in this country some eighty engineering schools in which courses in automotive engineering are being given. Most of these have laboratory facilities which can be or already are engaged in automotive research work. There has, however, been little if any effort to organize or correlate this work in such manner as to make it of greatest value either to the industry, which, in many instances, is called upon to donate the engine or other apparatus to be tested, or to the institution whose facilities and personnel are used.

Some universities regarded as leaders in automotive engineering education have already indicated a desire to arrange their programs of research in such manner as to avoid unnecessary duplication and to make their work of the utmost possible value to the automotive industry. They have, in fact, expressed willingness to cooperate in bringing about arrangements whereby a program in which each institution will have a definite prearranged part will be formulated and carried out in conjunction with the committee.

It is believed that the Research Committee of the Society can and will play an important part in formulating such a program and in seeing that it is carried through and the results compiled in a form that will make them of greatest value to all concerned. It has long been apparent that some organization can and should perform this function, and it seems certain that no organization can do it to better advantage than a properly constituted committee of the Society.

Those who are familiar with the work of the S. A. E. during the past few years will recall that the Council of the Society has appointed research committees which served during several recent administrations, and that a report on fuel utilization in present day engines was made at the last summer meeting of the Society by one of these committees. Aside from this little has come from the activities (or lack of activity) of these committees. This has been due in part to the fact that the Society office staff did not include personnel sufficient to carry forward on an effective scale work which could otherwise have been prosecuted. This personnel is now to be added to the staff of the Society, and the results which have long been considered possible of attainment should now be realized. The appropriation of $30,000 by the Council to be used in defraying the cost of maintaining the necessary organization, constitutes in the opinion of many members of the Society one of the most important actions ever taken by the Society. The ultimate good which results will naturally depend in large part upon the research organization built up as well as upon the support and co-operation of Society members and others in the work. If this co-operation is forthcoming as now seems likely, there appears to be little question but that the new activity will give much deserved credit to the Society and those responsible for instituting and prosecuting the research program.

Progress in Highway Educational Problems

President Burton of Michigan University believes that present generation will see highway development equal to railroad development witnessed by older generation and that education in this line is the great need of today. Other prominent speakers at Michigan Highway Conference.

By Clyde Jennings

THE movement for a wider appreciation of education in highways and highway transport gained a long step forward when Dr. Marion L. Burton, president of the University of Michigan, addressing a gathering of highway commissioners and engineers and students of the University, said in effect:

> We want it known that the University of Michigan appreciates the importance of the highway movement. I am not exactly certain in my statistics, but I expect to see between twenty and twenty-five billion dollars expended in highway construction during the next generation. It is my expectation that the generation now coming into manhood will see in its active life a movement in highway construction that will equal the development in railways that the older generation has witnessed. It is my belief that education in this line is one of the great problems of today and we hope that each student of this university shall leave here with an appreciation of this problem.

This statement, coming from the president of a leading western university, cannot but have a marked influence in educational standards. The University of Michigan has been one of the leaders in highway engineering and has been quick to appreciate the need of the complemental education—that in highway transport. Several other western universities have been and are working along the same line, but the eastern universities, in the main, have ignored the topics.

The occasion of this strong statement from Dr. Burton was a mass meeting which was a part of the Seventh Annual Conference on Highway Engineering and Highway Transport at the University of Michigan. Those in attendance at the five-day session were highway leaders of Michigan. On February 23 the members of the Permanent Committee on Highway and Highway Transport Education were guests of the University and of the Conference. The sessions of that day were under direction of Dr. P. P. Claxton, United States Commissioner of Education, and chairman of the committee. During the day the members of this committee explained to the members of the Michigan Conference the objects of their work. It was the second meeting of this sort the committee has held, the previous one being at Pittsburgh last November, when a similar exposition of the work was made to the school teachers of Pennsylvania. It is interesting to know that the meeting out of which this committee was developed was held at Ann Arbor last April.

The explanation of the work of this committee is simple. It is the thought of those responsible for the committee that there is a great need of engineers for the proper development of the highway plans now financed. Also when these highways are developed there will be a need of engineers to properly direct the traffic over them. This committee is encouraging proper schools to enter this field of education.

A highly interesting message of this session was contained in a paper read of Thomas H. MacDonald, chief of the United States Bureau of Roads, who said in effect that a highway in itself is of no value. It lacks the merit of a work of art, or of an article of certain intrinsic value. Its value is entirely in the service it renders to the community. On this theory he maintained that it is the duty of the promoters and builders of highways to measure their building by the traffic needs of the community which the highway is to serve.

The Committee was welcomed to the University of Michigan by Dean Cooley of the College of Engineering. The program included an address on "Highway Social and Economic Welfare," by Dr. Claxton, who insists that the educational and social advantages of highways will well repay their cost. Prof. C. J. Tilden, director of the Permanent Committee, explained the objects of the committee. Roy D. Chapin pictured the future of highway transport. George C. Diehl, Chairman of the Good Roads Board of the American Automobile Association, outlined a course in local geography for secondary schools which, he said, would be a great move toward a better understanding of the highway situation by the citizens of tomorrow. Harriet E. Beard, of the Detroit schools, told of the effective safety work being done there. Col. Mason H. Patrick told of the interest of the army in roads. Prof. Henry E. Riggs compared highways with railroads. Arthur H. Blanchard, professor of highway engineering in the U. of M., outlined effective surveys for highway transport. There was a largely attended dinner in the evening at which Dean Cooley presided and Tom Snyder and A. R. Kroh were speakers.

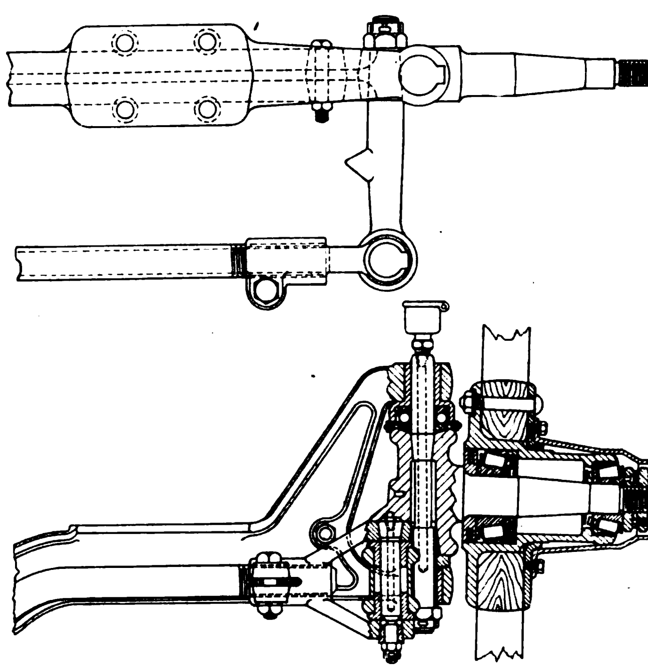
A SERIES of experiments, begun in 1914, but interrupted by the war, has recently been resumed in Brussels on the use of palm oil in internal-combustion motors. A Swedish two-cycle semi-Diesel engine was found which would run successfully on palm oil. According to analysis by Belgian chemists, palm oil is a mixture of palmitate and oleate of glycerine, with some variable quantities of palmitic and oleic acid. It contains about 95 per cent. of fatty acids and appears as a pasty substance of yellowish or salmon color. Its calorific power is estimated at 9,228 calories (Barthelot-Mahler), and it is inflammable at 210° C.

Two New Worm Gear Axles Arranged For Hotchkiss Drive

Housing and spiders are steel castings. Axle shaft, brake cams and some other important parts are of molybdenum steel. Both brakes internal expanding. Special lubricating features on both front and rear types.

By J. Edward Schipper

TWO new worm-drive axles incorporating a number of ingenious features, were shown at the Chicago show. They are the product of the Dunkirk Axle Co. The heavier of the two models are known as R-20 for the rear and F-20 for the front. They are similar in most respects to the smaller models R and F-15. The housing, housing spiders and hubs are made from electric steel castings. The worm and worm wheel are of generous proportions. Reduction ratios of 5.2, 6.25 and 7.75 are standard for model R-20.

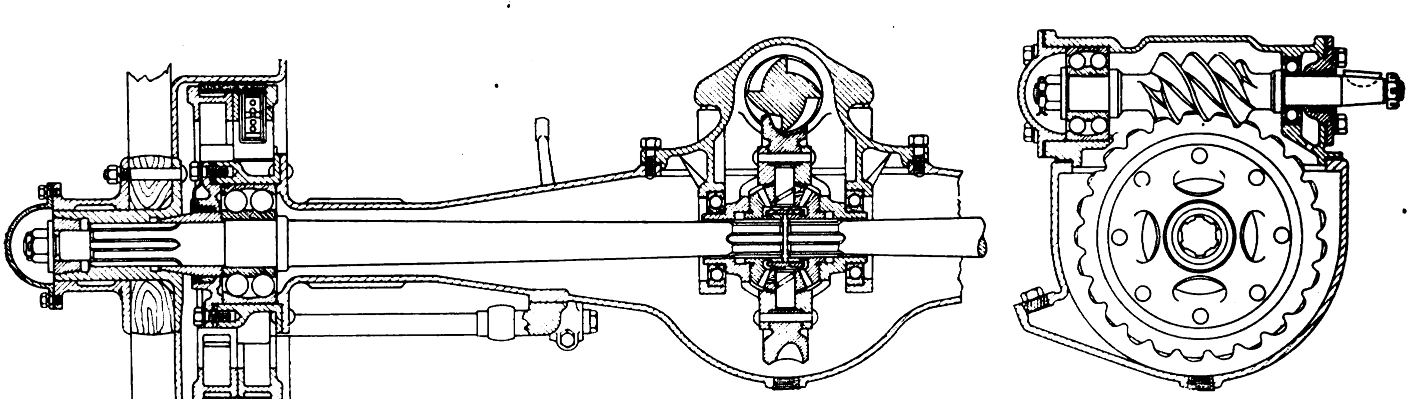


The Dunkirk model F-20 front axle for trucks

The differentials are of the bevel type and the side gears are splined to receive the ends of the axle shaft. The pinion, spider and side gears are all made from alloy steel, hardened and ground, for the bearings and splined fits. No bushings are used. The axle shaft, brake cams, brake supports and other important parts subject to stress are made from electric furnace, chrome molybdenum steel, heat treated and ground to size. Concentricity of the drum is secured by grinding on the inside braking surface and at the same time, grinding the center hole to size. The brakes are dual, internal expanding, of the wrap-up type. Each brake has an expanding and centering member, the lining and brake bands being separate pieces. With this feature it is possible to remove the brake lining rapidly for relining purposes without the use of wrenches, tools, etc., and also without the necessity for removing the entire brake shoe.

The brake levers are forgings from high carbon steel and are splined, giving an adjustment of about 6 deg. On the R-20 the levers are 8½ in. long. The axle is provided only for Hotchkiss drive and the spring pads for 2½ in. springs. A feature of the axle, however, is the provision for adjustment of the center distances by sliding the spring pads along the seat provided for the purpose.

The rear axles are of the semi-floating type and are ball bearings throughout. Oiling of all the moving parts is automatic from the splash within the housing, the wheel bearings are also lubricated from the same source. The brake cams and bearings are lubricated by wick feed and need attention but once a season. Another feature of the axle is the oil retaining packing which allows the entire wheel mounting to run in an oil bath without leakage to the drum. Dunkirk axles are produced in the plant formerly used by the Empire Axle Co. Production is scheduled to start at the rate of 500 sets a month.



Longitudinal and transverse sections of Model R-20 Dunkirk worm-drive truck axle

Rigid Construction and Clean Appearance Features of New Engine

High power output and good fuel economy claimed for engine recently tested in Detroit. Positive lubrication, overhead valves and camshaft, complete enclosure of moving parts, five bearing disk type crankshaft and easily detached accessories are among other interesting features.

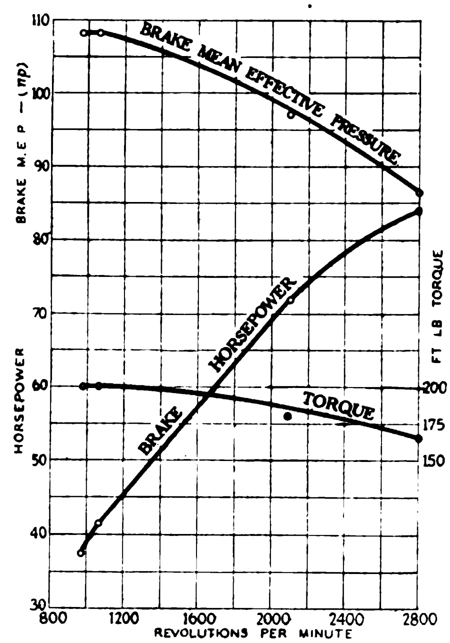
By J. Edward Schipper

AN interesting four-cylinder engine designed by Frank S. Spring and H. L. Elfes, has been under test for the past 2 yr., both on the dynamometer and in a car. Some rather remarkable results are claimed.

The power output from four cylinders of 3⅝ bore by 6¾ in. stroke with a displacement of 278 cu. in. is shown in the accompanying curve. It will be noted that the engine develops 85 B.H.P. at 2800 r.p.m. It weighs 400 lb., including accessories and clutch. The entire powerplant is 33 in. in length. The crankcase is very stiff and heavily ribbed. It supports a 5 bearing crankshaft of the disk type, 2¼ in. in diameter. The design permits the construction of a short engine, and is said to account to some extent for its lack of vibration.

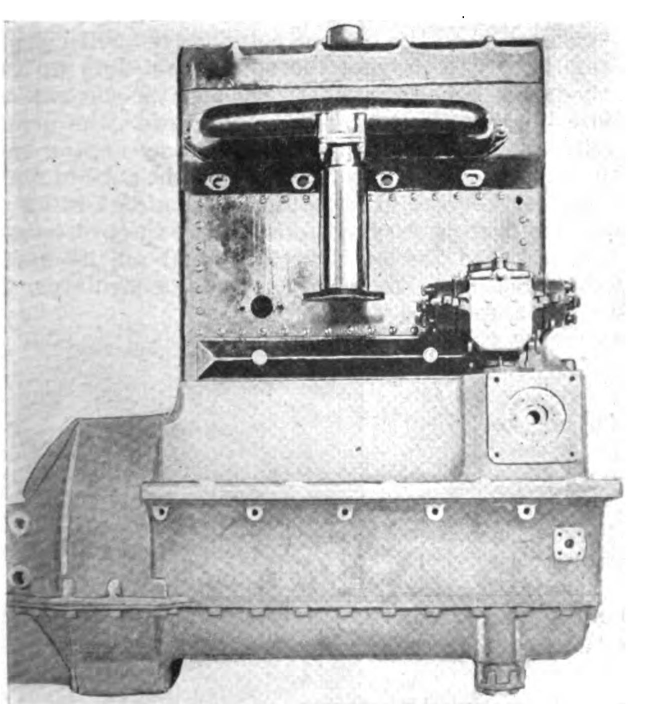
Tests of the engine mounted in a chassis were recently concluded by a large motor car builder in Detroit. The car carried five passengers and weighed 4300 lb. It was driven approximately 400 miles over roads in the vicinity of Detroit, averaging, it is claimed, 24 mi. per gal. In a later run of 1200 miles, with a load several hundred pounds greater than in the test mentioned the designer claims the car averaged 18 m.p.g. The route included the test hills in the vicinity of Pittsburgh and the car was driven wide open whenever conditions permitted.

All bearings are of generous proportions and it is said that their life is more than doubled by the use of the dry sump, in conjunction with high-pressure lubrication delivering a very large volume of cool oil, properly filtered, to all working parts. The latter are completely enclosed, in fact the only exposed moving part is the fan, which is carried on the forward end of the overhead camshaft.

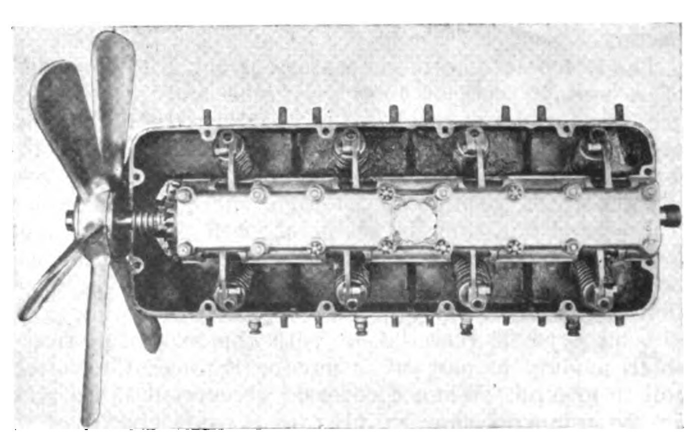


Performance curve of Spring engine

The oil pump is formed by meshing the gear on the lower end of the vertical shaft, which drives the overhead camshaft with the top gear of the short stub shaft driven by the crankshaft. This construction cushions the camshaft drive and helps to silence the valve mechanism. The



Intake side of Spring engine showing clean external appearance



Top view of Spring engine with valve cover removed

stub and vertical shafts are hollow. Oil is lead, through the vertical shaft, to the hollow camshaft and to the tubes upon which the rocker arms are located, oiling all bearings, and returning to the sump through passages cast in the cylinders and crankcase. Oil is led from the stub shaft through suitable passages to all of the main bearings, and thence through holes drilled in the crankshaft to the connecting rod bearings.

The cylinder walls and piston pins are lubricated by the oil thrown off from the connecting rods. A scavenging-pump is located externally on the front end of the oil pan. This pump returns the oil from the sump to the oil tank, which is separate from the engine, as fast as it accumulates. Baffle plates are cast integrally with the upper case to prevent excessive lubrication of the cylinder walls. It is claimed that under the most extreme running conditions, the temperature of the oil in the tank has never exceeded 100 deg. Fahr. Carrying the oil in a tank separate from engine has the advantage that it allows the use of an efficient filter of large area, that is easy to get at and clean.

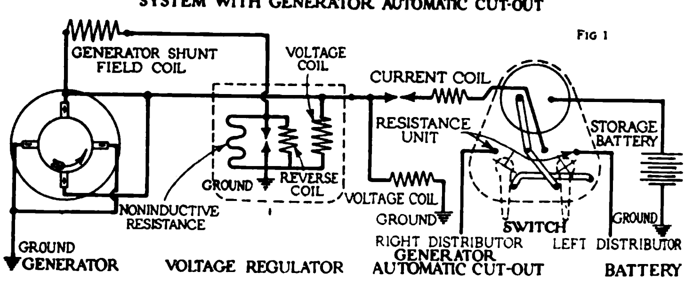
The removal of the top cover of the motor exposes the rocker arms and tappets for inspection and adjustment. The manifolds are external, and are easily removable; in fact, any of the units such as the distributor, generator, pump and starter can be removed by unscrewing not more than four nuts and without disturbing other units.

A Generator Cut-Out for Aircraft Use

A CUT-OUT, designed to be incorporated in the Delco airplane engine ignition system, has been on test at the laboratory of the War Department, Air Service, at McCook Field. The purpose of the cut-out is to break the circuit between the generator and the battery whenever the direction of current flow is reversed, i.e., when current starts to flow from battery through generator. This condition occurs in the Delco system at all generator speeds below approximately 1000 r.p.m., at which speed the generator ceases to charge. Since the battery and the generator are always in circuit in the Delco system except when the switches are shut off, a considerable drain on the battery results from the discharge of current through the non-functioning generator.

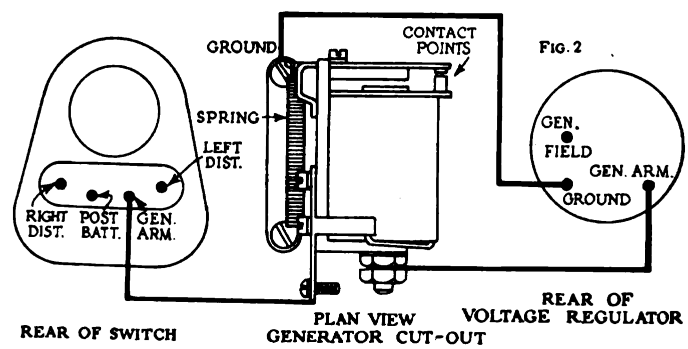
In the standard Delco system, the generator can be cut out at low engine speeds by shutting off one of the two switches in the low tension leads to the two distributor heads. This saves the battery, the capacity of which is limited, but necessitates operation of the engine on only one set of spark plugs at a time when, to prevent fouling, both sets of plugs should be firing. Cutting out the generator, when it is not charging, by means of the device tested, makes it possible to operate on both sets of spark plugs without unnecessarily draining the battery.

CIRCUIT DIAGRAM OF THE DELCO IGNITION SYSTEM WITH GENERATOR AUTOMATIC CUT-OUT



The Delco automatic generator cut-out, Fig. 1, consists of a voltage coil of fine wire, one end of which is grounded, and a current coil of heavier wire, both wound around an iron core. An armature with contact points is provided so that, with sufficient current flow from the generator through the voltage coil, this core will be magnetized and the contact points will close, thus completing the circuit between the generator and the battery. After the closing of the contact points the operation of the electrical equipment is exactly similar to the present type of installation with the exception that a small amount of current is flowing through the voltage coil to ground. When a reversal of current takes place due to stoppage, slow running, or a short circuit of the generator, a reversal of the magnetic flux around the current coil occurs and demagnetizes the iron core. The armature is drawn back by the spring and the contact points are separated, opening the circuit from the battery.

WIRING DIAGRAM OF DELCO AUTOMATIC GENERATOR CUT-OUT



The clearance between the contact points should be about 0.018 in. The voltage required for the closing of the contact points is regulated by the tension of a spring (shown in the wiring diagram, Fig. 2). The tension of this spring should be such as to allow the contact points to close at a potential of eight volts.

If the contact points of the voltage regulator separate before the contact points of the automatic generator cut-out close, then the cut-out points never will close, as the regulator will prevent the voltage building up sufficiently to get enough magnetization of the cut-out core to close the contact points. In other words, the generator will not be put into the circuit at any engine speed if the voltage regulator operates before the cut-out closes.

In the installation of the automatic cut-out in an airplane, it is first necessary to disconnect the present connection between the armature terminal of the switch, and the armature terminal of the voltage regulator. The wiring then required is shown by the wiring diagram, Fig. 2. The cut-out is fastened to any convenient point on the fuselage by the bracket shown in Fig. 3.

The automatic generator cut-out switches the generator into the circuit at about 500 r.p.m., at which speed the ammeter shows a discharge of about 3 amp.

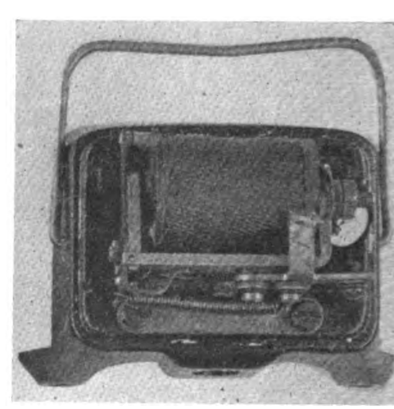


Fig. 3—Assembly view automatic generator cut-out

Passenger Cars Compared on Displacement Per Ton-Foot Basis

Wide variation in practice is shown to exist. Some makers allow nearly double the displacement per ton-foot allowed by others, thus enabling good acceleration and hill climbing ability at a sacrifice in fuel economy.

By P. M. Heldt

ONE of the fundamental factors in passenger car design is the piston displacement on high gear per unit of weight moved a unit distance. This can conveniently be expressed as the cu. in. of piston displacement per ton per foot of travel. In calculating the piston displacement, account is taken only of the displacement during the working stroke and in calculating the ton-feet, both the weight of the car ready for the road and the weight of the passenger load must be considered.

Let W be the weight of the car with load in pounds; d, the wheel diameter in inches; D, the piston displacement of the engine in cubic inches, and r the gear ratio on high gear. Then in one revolution of the rear wheels the car moves ahead

$$\frac{3.1416 \times d}{12} = \frac{d}{3.82} \text{ ft.}$$

The weight of the car and load is

$$\frac{W}{2000} \text{ tons,}$$

hence

$$\frac{W}{2000} \times \frac{d}{3.825} = \frac{W d}{7650} \text{ ton-ft.}$$

While the rear wheels make one turn the engine crankshaft makes r turns, and the total displacement of the pistons during these r turns is $2\, r D$, but as only every fourth stroke is a power stroke the useful displacement is $r\,D/2$. Hence, dividing the displacement by the ton-feet we get

$$\frac{\dfrac{r D}{2}}{\dfrac{W d}{7650}} = \frac{3825\, r D}{W d.}$$

In order to compare the practice followed by various manufacturers in this regard we have collected data on practically all American built passenger cars and tabulated it for convenient reference. To the weight of the car with full supplies ready for the road we have added 150 lb. for each passenger for whom seating capacity is

provided. From this total weight, together with the piston displacement, the gear ratio and the wheel size, the displacement per ton-foot was computed.

For more than one-half of all the cars this figure lies between 30 and 35, and the average of all the values is 32.8. A car having a high displacement per ton-ft., all other things being equal, would be able to ascend comparatively steep grades on high gear and would be capable of a high rate of acceleration, but it would consume more fuel per ton-mile than a car in which the displacement per ton-foot was smaller.

On a smooth, level road the resistance to vehicular motion at low speed is about 50 lb. per ton, this including frictional losses in the axle and those in the transmission due to the churning of the lubricant, etc. Therefore, while the vehicle moves one foot the work done in overcoming traction resistance is 50 ft. lb. per ton. The brake mean effective pressure of a gasoline engine under full throttle is about 75 lb. per sq. in. and the work of one cu. in. displacement therefore is

$$\frac{75}{12} = 6.25 \text{ ft. lb.}$$

There is, of course, a slight additional loss in the gearset and the rear axle when these are transmitting load, and, allowing for this loss, we may say that when the engine runs under full throttle, about 5.5 ft. lb. of work is done in propelling the vehicle for each cubic inch piston displacement under gas pressure. As 50 ft-lb. are required per ton-foot of transportation it would require a minimum of

$$\frac{50}{5.5} = 9.1 \text{ cu. in.}$$

piston displacement per ton-foot to propel a car at low speed on a hard, smooth, level surface. What we actually provide is 32.8 cu. in. displacement, from which it follows that the pressure on the piston in regular operation is only about

$$\frac{9.1 \times 100}{32.8} = 27.7 \text{ per cent}$$

of the maximum. The speed of the engine will be less than one-half that at which it gives its maximum output, and as power depends on both pressure and speed, the power developed by the engine when driving at 15 m.p.h., say, is not much more than 10 per cent of the maximum power.

Comparison With Small European Car

It is of interest to compare with the above figure of 32.8 cu. in. per ton-ft., the corresponding figure for a Fiat Model 501, a car evidently designed for economical use of fuel. One of these cars took part in an Australian fuel economy contest, and won first prize in the members' event for cars of 15 hp. or less. This car did a distance of 31.344 miles to the gallon and 36.438 ton miles per gallon, hence it weighed with load 2325 lb. It has a four-cylinder engine of 65 x 110 cu. in. bore and stroke, a gear ratio of 5.1 to 1 and 760 x 90 cu. in. wheels, making the wheel diameter practically 30 in. The piston displacement figures out to 89 cu. in. Hence the cu. in. displacement per ton-ft. is

$$\frac{3825 \times 5.1 \times 89}{2325 \times 30} = 24.9.$$

This is 24 per cent less displacement per ton-foot than that of the average American car.

Nickel Plating Aluminum

We have received several inquiries regarding the subject of nickel plating aluminum. The following item in this connection should therefore prove of interest. —THE EDITOR.

A. Mazuir describes a process of nickel plating which has given him the best of results as regards both adherence of the layer formed and fineness of the deposited metal. This process consists of the following four operations: Decrustation, cleaning of the surface to be nickeled, immersion in a bath of a metallic chloride, nickeling at a high-current density.

The piece of aluminum is lowered for a period of two minutes, while cold, in a bath containing 8 grams of NaO and 30 grams of cyanide of potassium per liter. With this concentration the aluminum is not appreciably attacked; in fact, the effect on the metal is so slight that even threaded and calibrated parts can be handled. The piece is washed in an excess of water and is then energetically brushed with a solution containing 4 parts of water to one part of lime. The surface in this way acquires a brilliantly white appearance without streaks or spots.

The piece is washed and brushed once more to get rid of all traces of lime and is then immersed in an acid bath of some metallic chloride. It has been found that chlorides of manganese and of iron give better results than any other chlorides. Thus with a bath of the following composition—

Hydrochloric acid of 22 deg.	350 cu. cm.
Manganese	2 grams
Water	650 cu. cm.

there was obtained a coating of nickel without spots and very adherent. With a bath of iron chloride containing 3 grams of iron per liter, the results are slightly less satisfactory; the deposit is then a dull white.

During the immersion there is formed on the surface of the piece a metallic coat resulting from a chemical transposition between the iron and the aluminum; fine particles of iron become fixed on the aluminum and thus form an intermediate, very tenacious layer between the aluminum and the nickel.

The immersion in this acid bath lasts two or three minutes. The piece is washed in a low-pressure stream and is then placed in the nickeling bath proper. A bath of the following composition was used:

Simple sulphate of nickel	120 grams
Double sulphate of nickel	50 grams

This bath must show 12 to 13 deg. Baume, and must be completely neutral. The anodes consist of laminated nickel plates. The pressure should vary between 2.5 and 3 volts. In going beyond these limits there is obtained a deposit which does not adhere and which flakes off. The current density should vary between 1 and 1.5 amperes per square decimeter.

The piece is left in the bath for an hour and a half, if it is of average size. It is then washed in boiling water and dried by compressed air. The layer of nickel obtained by this process has a remarkable adherence and an incomparable whiteness and polish. Sheets of aluminum thus nickeled resist the most energetic torsion without peeling off.—*La Technique Moderne.*

Parts and Accessories at the National Tractor Show

Recent developments in air cleaners, traction devices for wheeled tractors and automatic hitches. Rubber tired wheels for road work, line control mechanisms for Fordson tractors and a drawbar pull indicator.

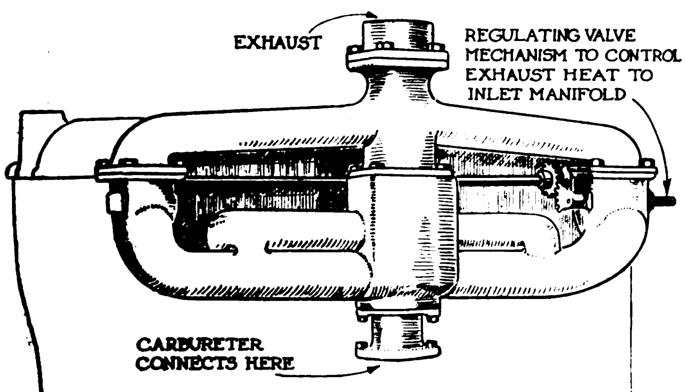
By P. M. Heldt

MOST of the stands around the walls at the tractor show were devoted to parts and accessories, and there was among these exhibits at least as large a percentage of novelties as among the tractors themselves. There were evidences that the heavy fuel problem, the air cleaner problem, the driving lug and other problems of the tractor industry had received due attention during the past year. There were also the usual number of devices intended to improve the Fordson tractor or adapt it to particular uses.

The Climax Engineering Co. exhibited engines with a new type of manifold, known as the K-317 manifold. This is a combined inlet and exhaust manifold in which provisions are made for regulating the amount of heat imparted by the exhaust gases to the incoming fresh charge. Referring to the sketch herewith, the inlet and exhaust manifold are in a single casting, and there is a hot spot or exhaust-heated portion of the inlet passage at the center. There are two outlets from the exhaust manifold, one being through this exhaust jacket and the other from the ends of the straight, horizontal portion of the manifold, through a cast pipe connecting with the outlet from the exhaust jacket at the center. There are damper type valves at the joint of the exhaust manifold with the return pipe, both on the same shaft, which are controlled by means of a pinion and sector mechanism. By closing these damper valves, all of the exhaust gases can be passed through the exhaust jacket, whereas by opening them more or less, almost any desired fraction can be shunted around the jacket.

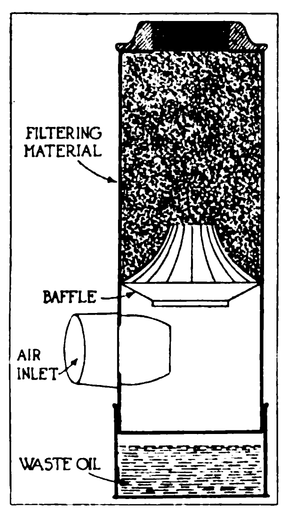
New Air Cleaners

Two new air cleaners were shown, the Pomona Vortox and one manufactured by the United Manufacturing and Distributing Co. The first, illustrated in section herewith, is of the combined centrifugal and filtering type. The air enters through a tangential inlet and is thus given a

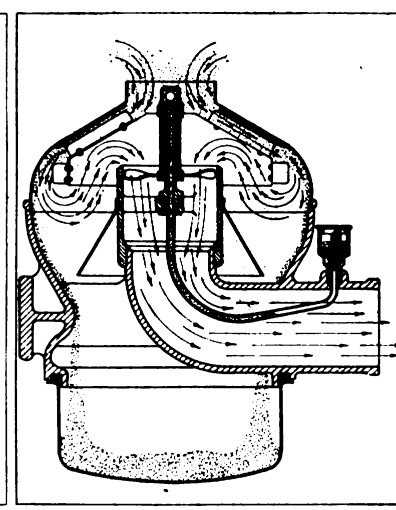


New Climax manifold with control of the exhaust heat

whirling motion, which causes the air to collect close to the outer wall, and as the communicating passage between the lower and upper chambers is at the center of the cylindrical chamber, the dust falls to the bottom, where it is absorbed by stale crankcase oil contained in a removable cup. In the upper part of the cylindrical chamber there is a filter of fibrous material through which the air has to pass on its way to the carburetor, and the passage between the lower and upper parts is of such design that it gives a further centrifugal motion to the air. Thus the air is subjected to two centrifugal cleanings before it is passed into



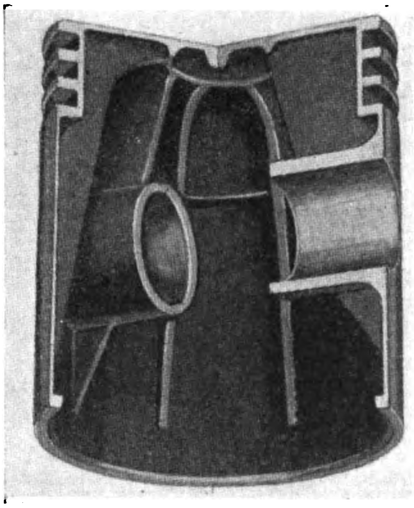
Pomona Vortox air cleaner



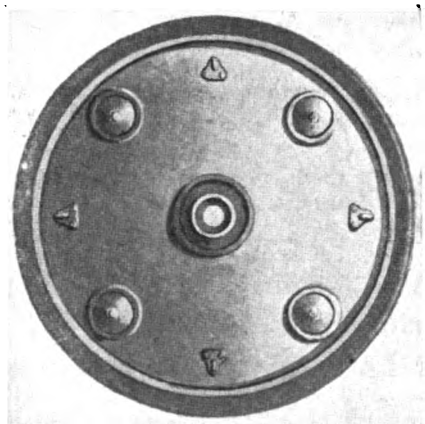
United Mfg. Co. air cleaner

the filter, with the intention of preventing rapid clogging of the filter.

The air cleaner of the United Manufacturing and Distributing Co. is of the dry centrifugal type. As may be seen from the sectional view, the air enters at the top and immediately strikes a rotary baffle which is provided with two sets of fins. The fins give a rotary motion to the air current, throwing the dust against the walls of the chamber. After passing the edge of the baffle the air is compelled to reverse its direction of motion, passing upward and inward to enter the L shaped outlet of the cleaner. The hub of the rotary baffle is mounted centrally in the outlet and carries a driving fan at its lower end, by which the baffle is set in rotation. The dust drops down the walls of the cleaner and collects in a readily removable cup, while the clean air passes out through the side of the cleaner. In the drawing an oil cup with wick feed to the baffle bearing is shown, but this has been replaced by an oil-less bushing in the hub of the baffle.



Clark-Turner light cast iron piston



W. & K. rubber-tired wheels for Fordson tractors

The Clark-Turner pistons, which are cast iron pistons of unusual lightness, were shown by Litter's Motor Machine Shop. These pistons are made with very thin walls and a considerable number of ribs to strengthen the piston and help carry the heat from the head to the skirt. The advantages are those of lighter reciprocating parts. There is less vibration and less strain, owing to the reduction of the inertia forces.

Whitehead & Kales Co. showed rubber-tired wheels for use on Fordson tractors to adapt them for operation on the roads. So equipped the Fordson can be used for hauling loaded trailers on the road, for switching freight cars, for drawing snow plows, etc. The rubber-tired tractor has been found useful by municipalities, factories, contractors, coal and building supply dealers, and road builders. The wheels are made of metal disks, are hollow, and the rear ones can be loaded either with water, sand, cast iron chips, or cement to increase their weight and thus get additional traction. One of the disks is made with four hand holes through which the loading material can be introduced. Each disk is also provided with four hooks for the convenient attachment of anti-skid chains.

The rear wheels are equipped with 40 x 5 in. S. A. E. standard solid rubber tires, and the front wheels with 24 x 3 in. The wheels and tires are shipped fully assembled, ready to be placed on the tractor.

The Whitehead & Kales Co. has also brought out a new design of tractor wheel which combines lightness with great lateral and radial strength. The rim is made of rolled steel with inwardly turned flanges, but the rim proper, instead of being made flat, is formed with two substantial corrugations. The spokes are arranged so that the two sets cross; at their inner ends they are riveted to steel disks cast into the gray iron hubs, and at their outer ends they are riveted to the rim at the corrugations—not to the flanges. This obviates the weakening of the flanges by rivet holes and adds considerably to the strength of the wheel.

The Miller traction tread is a device which is claimed to give with a wheel tractor some of the advantages of the creeper type. There are seven cast steel shoes, cast integrally with the links of the chain. The links are joined together with hardened, cold rolled steel pins, fitted with rollers, which pass through elongated holes in the ends of the links. These elongated holes allow a reciprocating action to take place between the ends of the links. Upon this reciprocation depends the proper movement of the separate links as they pass over the sprocket. At the center of each link there is an additional pin with roller which takes the thrust from the sprocket teeth.

The complete tread unit is mounted on a cast steel sprocket which is secured to the side of the regular tractor wheel. The tread can be removed by removing one pin, stretching the links flat on the ground and rolling the tractor off. The sprocket does not interfere with the operation of the round wheel. This tread is made especially for the leading makes of garden tractor.

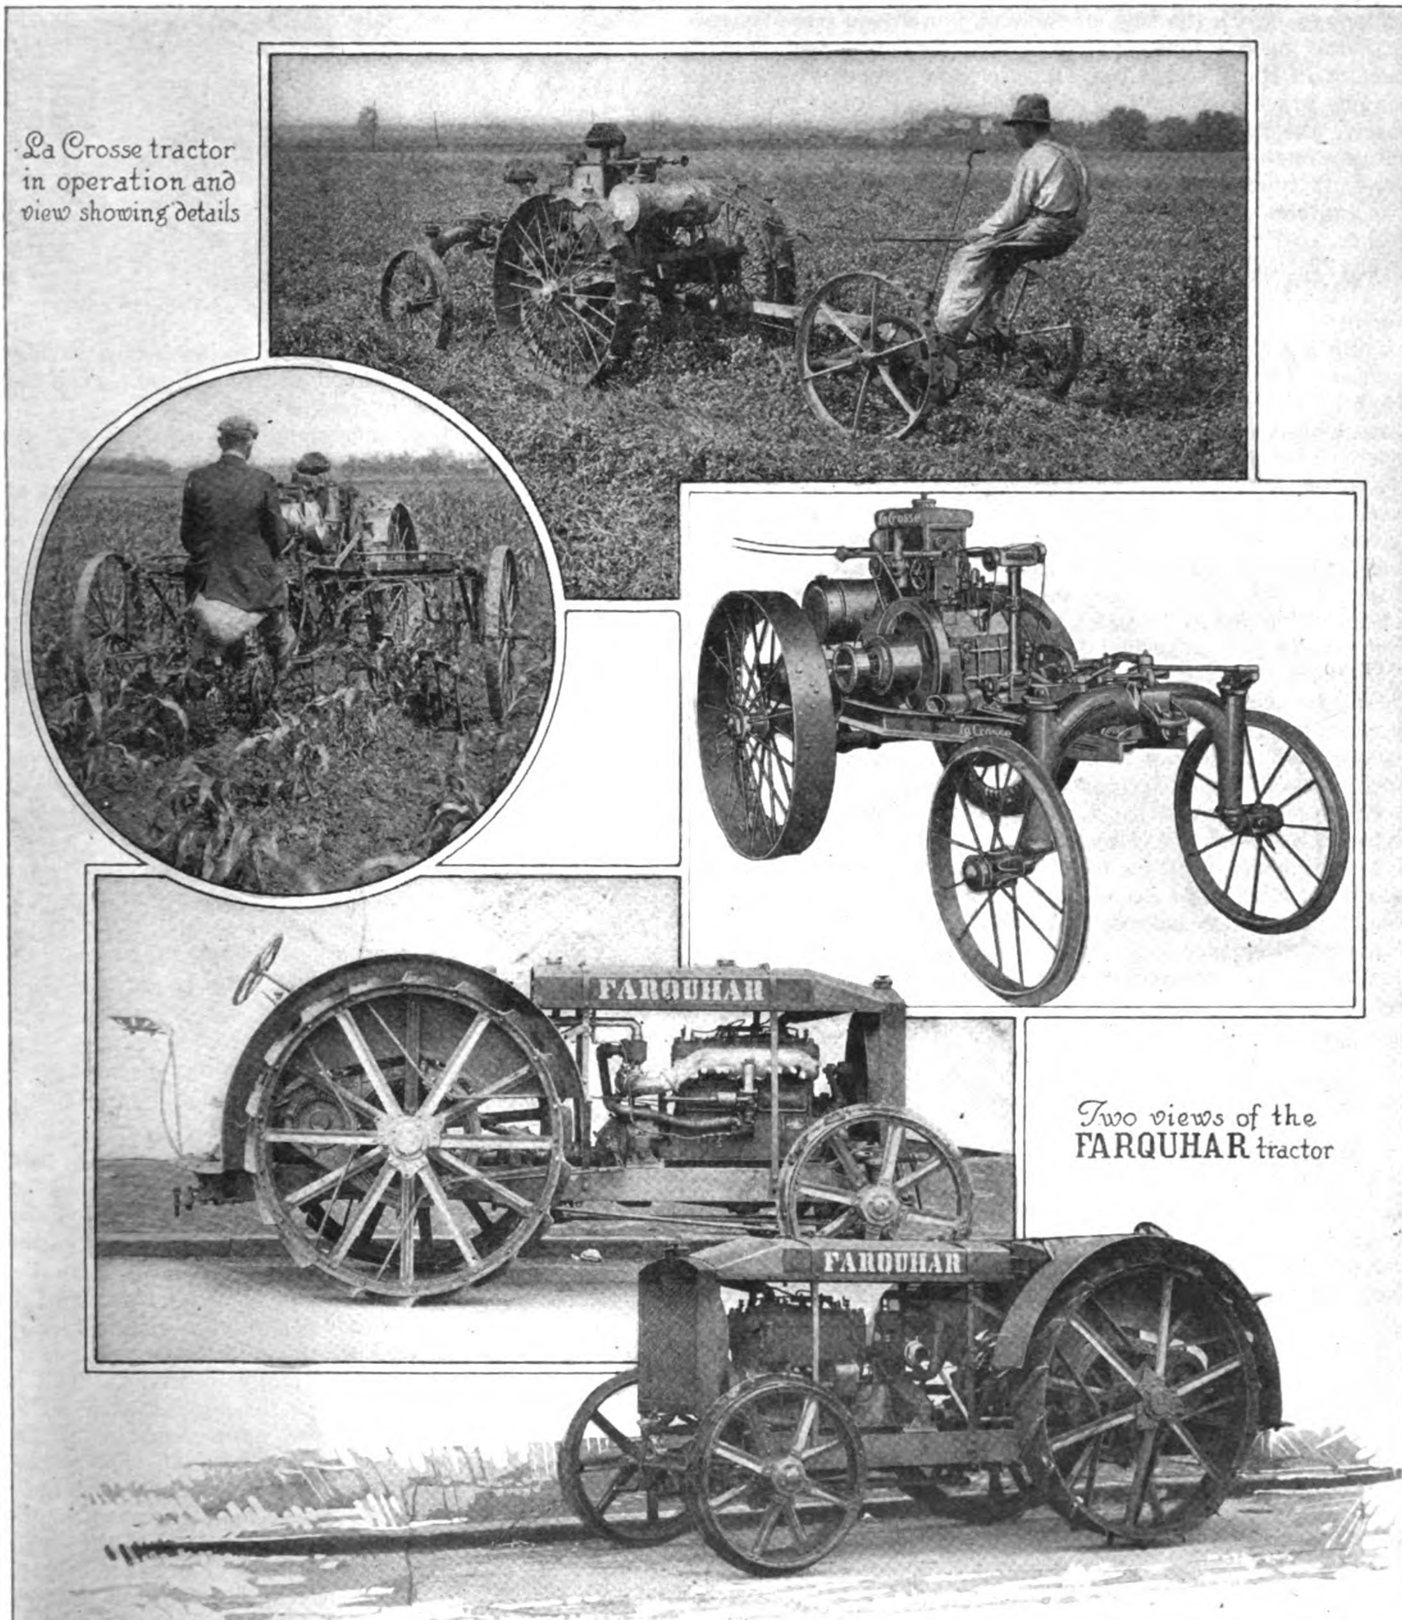
Two New Tractors Exhibited at Recent Show



La Crosse tractor in operation and view showing details

Two views of the FARQUHAR tractor

The above illustration shows the Farquhar 15-25 and the new La Crosse tractor, both of which were shown for the first time at the recent Columbus tractor show. Descriptions of these tractors appeared in our issue of February 24, but the photographs did not reach us in time for insertion in that issue. As will be seen from the illustration, the feature of the La Crosse is the line drive, which makes it possible for the driver to ride on the implement and saves the services of one man when operating grass mowers, self-binders and manure spreaders. An unusual feature of the Farquhar is that it is spring-suspended at both the front and the rear

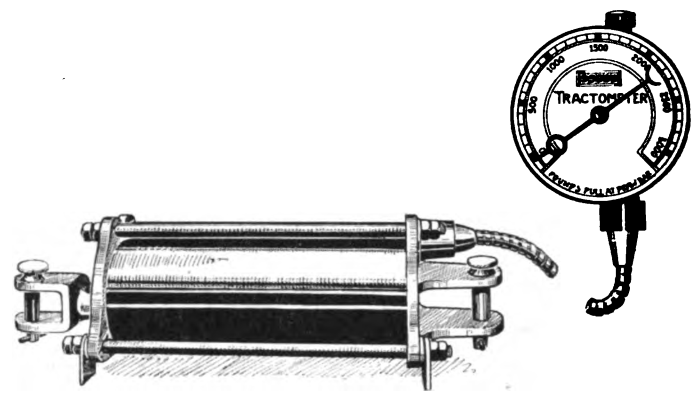
The Bentz tractor lugs were exhibited by the Lebanon Steel Foundry. These lugs embody a quick detachable principle. When applied to the wheel, the lug is placed on the rim and drawn to one side so that the channel of the lug engages with the edge of the rim, and at the same time with the lug previously put on. The next movement puts the lug in its final position, interlocking it securely with the one previously applied, while the other end is ready to receive the next lug. The lug is made in two styles, one being a one-unit type and the other a two-unit type. The two-unit type is suitable for both road and field work. The end lugs are provided with "eyelets" and are bolted together, so that a single bolt suffices for the assembly.

The Taco Calumet tractor hitch is a device which absorbs the shock on both the plow and tractor when plowing in stony soil. It consists of a hitching member comprising a coiled spring which compresses as the draft increases. On tractors on which the clutch pulls out, the hitch is installed to operate a lever when the plow encounters an obstruction, this lever being connected to the clutch lever. Thus the tractor is stopped when a rock is struck, for instance, but the plow is not disconnected. This hitch was designed to do away with the troublesome wooden pin. A similar device, known as the Tractorstop plow hitch, was exhibited by the Meili-Blumberg Co., Inc.

A governor for Fordson tractors was exhibited by the Krebs-Wells Controller Co. This was said to be a true multi-speed controller and to govern the engine at whatever speed it is set to. The governor is mounted at the forward end of the engine and its connection to the throttle is arranged in a neat manner. Similar governors have been made for truck engines since 1914. The Hartley Governor Co. also showed a governor for Fordson tractors.

Among the specialties for Fordson mention should be made of two line control devices and a front hitch.

The Kokomo Electric Co. showed a new magneto for single cylinder engines. This magneto is of the high tension type and is claimed to be dust and moisture-proof. Among the features of construction may be mentioned a laminated armature, mica condenser, platinum or tungsten contact points, windings treated with insulating varnish and taped with oiled silk, hard rubber collector ring and brush holder and Esterline magnets.



Drawbar unit and indicating head of Tractometer

A device designed for measuring the drawbar pull exerted by a tractor in plowing or other drawbar work was exhibited by the Tractometer Co. and is known as the tractometer. It comprises a drawbar unit in the form of a cylinder with cast heads, each with a clevis for connection between the drawbar and the plow or other implement. This drawbar unit incloses the spring which transmits the drawbar pull and the compression of which measures the pull. An overload stop is built into the cylinder and is provided with a cushion for absorbing the jar due to overloads. This unit is furnished with a leather handle for easy handling.

From the drawbar unit a flexible cable extends to the indicating head on which the compression of the spring, and hence the drawbar pull, is indicated. It is claimed that this flexible connection between drawbar and indicating instrument eliminates errors in the readings due to the vibrations of the drawbar. This instrument is very much cheaper than the usual forms of hydraulic traction dynamometer, and it is believed that even tractor owners will purchase the instrument.

A Windshield Designed to Exclude Rain

A WINDSHIELD designed to exclude rain, snow and cold air has recently been devised by W. D. Crowell. This shield consists of two-glass sash and a sun-visor arranged in the manner shown in Fig. 1. When set in the position shown the air stream is deflected upward over the top of the vehicle, and is said to carry with it rain and snow and also to ventilate the enclosure back of the shield by drawing air outward in the manner indicated by the arrows. Gutters placed at the lower edges of the visor and the upper sash carry off to the side any water which runs into them. When in the position shown, the clear opening is about 2 in.

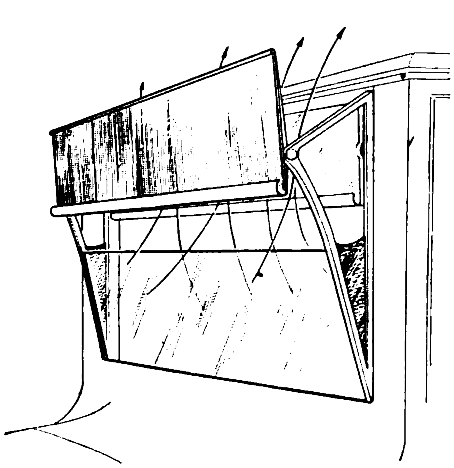


Fig. 1

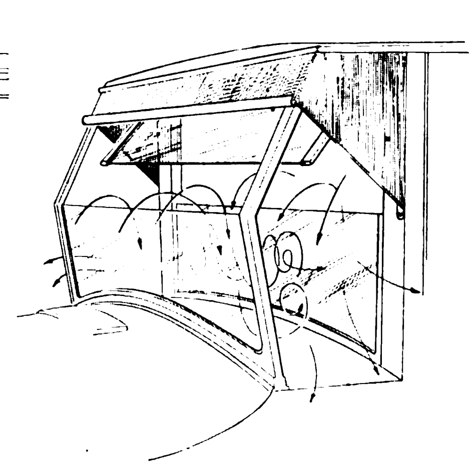

Fig. 2

Another design of windshield, called the down-draft pattern, is shown diagrammatically in Fig. 2. This is composed of three-glass sash and a sun-visor set, for use in stormy weather, in the position shown. Air carrying snow or rain is said to be deflected in the manner shown by the arrows without entering the space back of the shield. The space between the two lower sash is open at the ends to permit escape of the air which enters it. The two lower sash can be fixed if desired, the upper glass only being pivoted.

Patents to cover both designs shown have been allowed or are pending. The Zenite Metal Co. has been licensed to manufacture under these patents.

Diesel Type of Engine for Motor Vehicle Work

Has two pistons in same cylinder and works on two-stroke cycle. Injection results from explosion in ignition chamber connected with combustion chamber by narrow passage. Separate air compressor not required.

A SINGLE cylinder two-piston engine working on the two-stroke Diesel principle but without an air compressor has been built by the Deutsche Automobil Constructions Gesellschaft. The engine employs the Steinbeker method of fuel injection. According to our German correspondent, the first engine is now undergoing tests. The cylinder has a bore of 130 mm. and a stroke of 160 mm. per piston, making the combined stroke of the two pistons 320 mm. This is equal to a single cylinder engine of 5.12 in. bore and 12.6 in. stroke. The output is said to be 35 h.p. at 850 r.p.m., which corresponds to a brake mean effective pressure of 63 lb. per sq. in. The over all length is only 37⅜ in. and the weight per horse power 22 lb., which is about the same as that of the average truck engine.

It is obvious that if the ordinary Diesel engine were to be built for automotive purposes the most difficult problem would be the construction of the multi-stage air compressor, which must furnish air pressure up to 1000 lb. per sq. in. This is eliminated in the Steinbeker engine, and a simple injection system substituted therefor. A sectional view of the Steinbeker fuel injection mechanism is shown in the cut. To the cylinder head is secured a small vessel called the ignition chamber, which communicates with the combustion chamber through a central passage called the firing passage. The cylinder is provided with the usual inlet and exhaust valves. One fuel jet delivers into the firing passage and another into the cylinder direct. When applied to a four-stroke engine this injection mechanism operates as follows:

During the first inward stroke of the piston pure air is drawn into the cylinder, and during the following outward stroke it is compressed and some of it enters the ignition chamber, the pressure reaching a value of 450 to 500 lbs. per sq. in. During the end of this stroke fuel is injected into the firing passage and carried along by the rush of air into the ignition chamber. When the outer dead center position is reached the charge in the firing chamber is ignited by contact with the hot walls thereof, and the pressure in the ignition chamber then reaches 1100 to 1400 lbs. per sq. in. As a result a column of flame is projected into the combustion chamber. This carries along the fuel now entering the firing passage, spraying it into the combustion chamber. When the piston has traveled a short distance from the beginning of the power stroke the fuel supply is cut off and thereafter the charge expands until the end of the stroke. During the next outward stroke the piston expels the spent gases through the exhaust valve, which is then open. It will thus be seen that in the Steinbeker engine the pressure created by the partial explosion in the ignition chamber takes the place of the high pressure produced by the air compressor in the ordinary Diesel engine.

Adjustable and Folding Seats Used on Many British Cars

Need for adjustable feature on driver's seat is met by several types of design described in this article. Front seats are also made detachable in some cases thus rendering more accessible parts located under the floorboards. Folding backs facilitate access to rear seats.

By M. W. Bourdon

FOR many years, even prior to the war, there has been evident a growing demand among British motorists for a means of adjusting the front seats so as to afford the most comfortable position for drivers of various leg lengths. This demand is now being met by an increasing number of makers, some content to make the two seats at the front an adjustable unit, others providing separate seats independently adjustable. The latter arrangement does not appear to be necessary to comply with requirements; it makes a more costly job if the degree of comfort afforded by the fixed seat be retained, and so long as the driver be conveniently placed for pedal operation, his companion's position does not matter, within reason.

Austin has quite a good and simple design of unit seat, as shown in Fig. 1, though there are but three definite variations available. The seat is located primarily by notches in the frame engaging with a stud projecting from the floor at each side, and is locked by slotted plates right and left just below the elbow line. The seat bottoms are hinged to tip up as shown, but this feature is only provided to render more accessible certain chassis details beneath the floorboards—the fuel tank, for example, which has its filling spout projecting through the floor under the right-hand seat.

Riley cars also have the unit seat arrangement (Fig. 2), the fore and aft adjustment being locked by a wing nut under each loose cushion, the latter also being secured, as shown, by similar means. The space below the cushions in this case provides accommodation for a few tools, jack handle, tire pump, etc.

Standard cars have separate seats independently adjustable as shown in Fig. 3. T-head screws locate them. Two threaded sockets are provided in the floor so that the range of adjustment afforded by the slot is considerably extended, unnecessarily so, in fact. The back upholstery of these seats is peculiar, for the hinged frame has a broad fabric band laced horizontally around it, while the upholstery is detachable, being held in position by a long inverted pocket which slips over the top of the frame. The Standard is one of the light four-seaters developed in England. The back of the front seat is hinged to enable an unrestricted entrance to the rear when the seats are placed well back to accommodate tall occupants. Here also the box-like base of each seat affords tool space. No springs are used in the back padding, the flexibility of the frame being considered sufficient.

In another light four-seater, the Enfield-Allday, one very wide door is provided at each side, and, to enable front and back passengers to have easy access the separate front seats have hinged backs and bases as shown in Fig. 4. Both seats are located by a cross member secured, as indicated, by means of a slotted tongue and wingnut. This form of seat is obviously applicable also to sedan bodies with single doors, a variation of the Enfield arrangement appearing in the Arrol Johnston sedan (Fig. 5). Here the passenger's seat is non-adjustable fore and aft, though detachable and provided with hinged back and base. The driver's seat differs in having fore and aft adjustment and being located by rails and a pin lifted from or pushed into a floor socket by a forward projecting lever.

Some of these adjustable seats, it will be noticed, are distinctly low in height from floor to top of the cushion. The Albert (Fig. 6) is more so than most, being only 9 in. high at the front. These seats are, in fact, little more than cushions with a folding back attached to them. The baseboard is secured to the floor by cap screws.

None of the examples illustrated are so elaborate in construction or finish as those fitted to high class sedan bodies, for the latter are more in the nature of movable armchairs. Those specimens selected for mention here are applied to cars of quite moderate price (as prices run nowadays) and are standard in the British cars named, which sell at from $3,000 to $4,000 with four or five-seated bodies.

A more elaborate type of seat with anchorage and means of adjustment favored in many high class bodies is that shown in Fig. 7, where each separate seat has metal panelling on a well upholstered framework. The seats run on rails and are located by studs dropping into the central runner and operated by the levers shown. This is a pattern frequently observed on specially built sedan bodies, the covering of the cushions and upholstery being usually Bedford or corded cloth.

Besides the advantage which adjustable seats afford in respect of leg reach, a consideration by no means unimportant is the fact that the front seats being removable, the floorboard can be made removable also to enable the chassis details below to be reached with ease. This fact has been borne in mind in several cases where adjustable seats are fitted, though the advantage concerns mainly those chassis in which the gearset is mounted amidships, and is, therefore, usually located, with the transmission brake and propeller shaft joint, under the front seat.

Users who have had experience with adjustable and removable seats point out the great desirability of the seats, whether they are separate or formed as a unit, fitting closely to the body sides, otherwise the front passengers suffer from additional draughts which are en-

Fig. 4. Enfield-Allday has one wide door. Seats have hinged backs to facilitate access.

Fig. 5. Arrol Johnston sedan has non-adjustable passenger seat with base and back. Driver's seat is adjustable.

Fig. 6. Folding seats on Albert car are only 9 inches high and are attached to floor by cap screws.

Fig. 7. Type of adjustable seat used on many high grade cars. It slides on rails and is located by studs operated by levers.

couraged to swirl around the legs and between the seats and the body.

Another point to be borne in mind is that a closely fitting loose seat, unless it is in some way attached to the sides of the body, is liable to hammer and rattle against the latter when vibration and frame distortion have their natural effects. Hence the Austin arrangement (which, by the way, is not unique), wherein the seat is fastened to the body framing, is not without special merit.

High Thermal Efficiency in Airplane Service

Advantages and disadvantages of two types of mixture control devices are discussed, and test data showing the fuel saving made possible by the use of higher air to gas ratios are given, as are also particulars showing the corresponding effect on the power developed.

By S. W. Sparrow*

DETAILS of design of certain foreign engines, whose high *average* efficiency has received much publicity, are of interest. During an examination of these engines at the Bureau of Standards, an unusual type of air-fuel ratio control suggested itself as a possible source of the high efficiency. Fig. 2 shows this type diagrammatically, while Fig. 1 is typical of a construction common on American engines. In the latter type, the rate of fuel flow is altered to produce the mixture ratio changes. This can be accomplished by restricting the fuel passage or, as shown in the figure, by changing the head producing flow through the agency of a valve in the passage connecting the float chamber with the carbureter throat. Similar results are frequently obtained by a type similar to that shown in Fig. 2, but so proportioned that the mixture ratio change is not accompanied by any appreciable change in the quantity of charge supplied. In contrast, Fig. 2, to typify the foreign construction, is assumed to be so designed that the leaning of the mixture is always accompanied by an increase in the amount of charge supplied. This can be effected by interconnecting the throttle with a device for altering the size of the fuel orifice or, as shown in the figure, by an auxiliary throttle which admits a very lean mixture of pure air. For this auxiliary throttle to be effective, the carbureter throat must offer a considerable restriction to air flow. The important difference between the two types is that in the one shown in Fig. 1, the change in power produced by a mixture change is due almost entirely to the change in power-producing ability of a unit weight of the mixture, while in the other type there is always the additional effect of the quantity change necessary to bring about the change in mixture quality.

Fig. 3 indicates the economy that is possible with the type shown in Fig. 1. The curves shown in full lines are based on tests of an 8-cylinder aviation engine at an altitude of 5000 ft. and a speed of 1600 r.p.m. It will be noted that a decrease in the specific fuel consumption of over 15 per cent is secured when the mixture is leaned, until there is a decrease of 10 horsepower in 150, i.e., 7 per cent. Unquestionably then, so long as this type of control has sufficient range, its proper handling will result in a marked fuel saving. Will it receive such handling? To realize how unlikely this is, it must be remembered that continuing the mixture impoverishment will ultimately result in a blowback in the carbureter, a likely cause of fire. Knowing that safety depends on not reaching this condition and lacking knowledge as to how close to it a given carbureter setting is, the pilot has every incentive to adjust away from, rather than toward, maximum efficiency. Even were it possible to eliminate the fire hazard, the problem would be far from solved. In flight, the only measure of performance ordinarily available is that of power as indicated by the engine speed. In spite of all evidence as to the benefit of the lean mixture from the standpoint of efficiency, such an adjustment, inasmuch as it results in lower power, the only gage of performance available to the pilot, is bound to be unnatural.

*Technical Note No. 39 of the National Advisory Committee for Aeronautics, abbreviated. Based on tests made by the Automotive Power Plant Section, Bureau of Standards.

DIAGRAMATIC ILLUSTRATIONS OF TWO METHODS OF VARYING FUEL TO AIR RATIO.

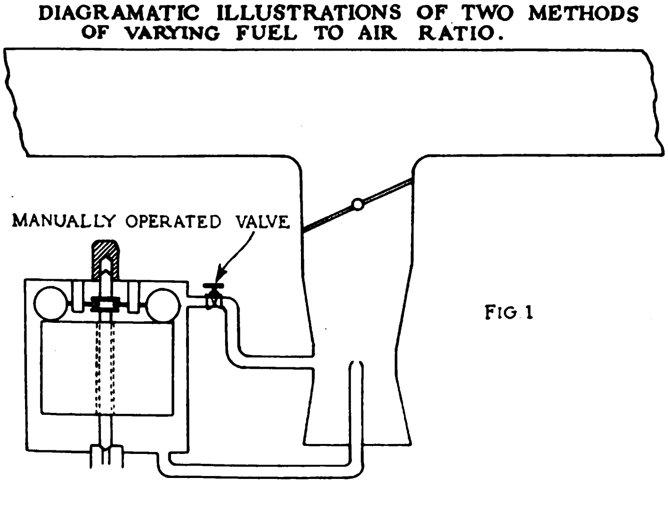

FIG 1

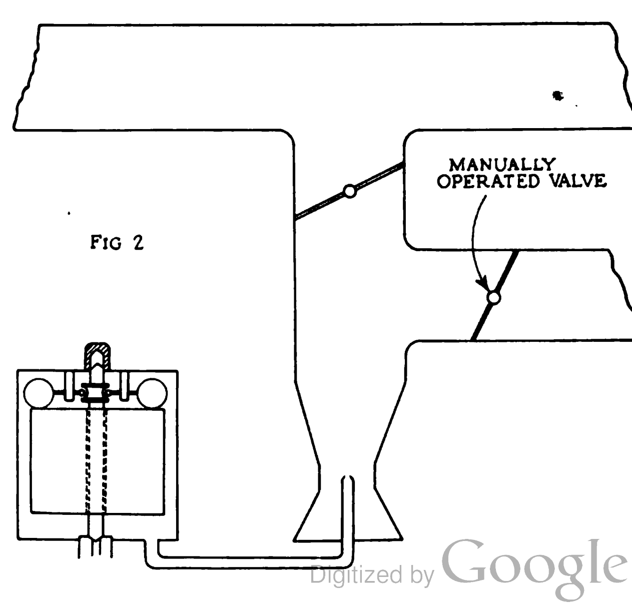

FIG 2

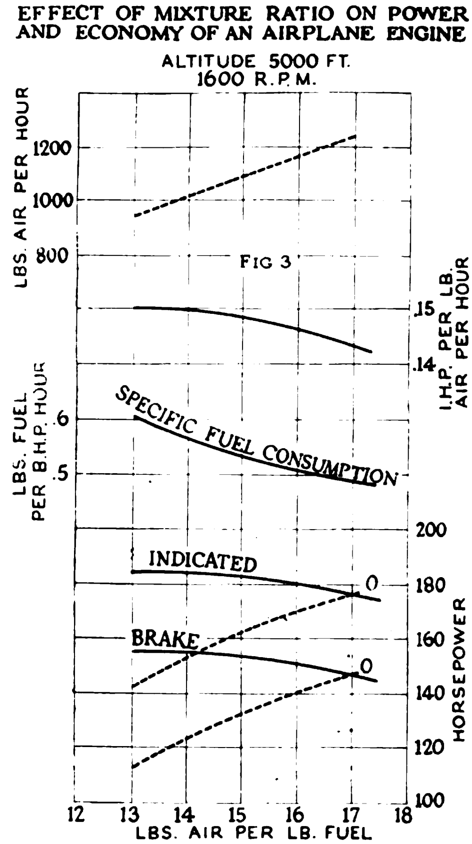
The explanation of the disadvantages of the first type makes clear the merits of the second. With this, as the mixture becomes of poorer quality, the amount supplied is increased. The natural adjustment, that for maximum power, will be the one at which the decrease in quality ceases to be overbalanced by the increase in quantity. If the design is such that this point is always reached before the mixture becomes lean enough to cause a blow-back in the carbureter, there is a considerable safeguard against fire.

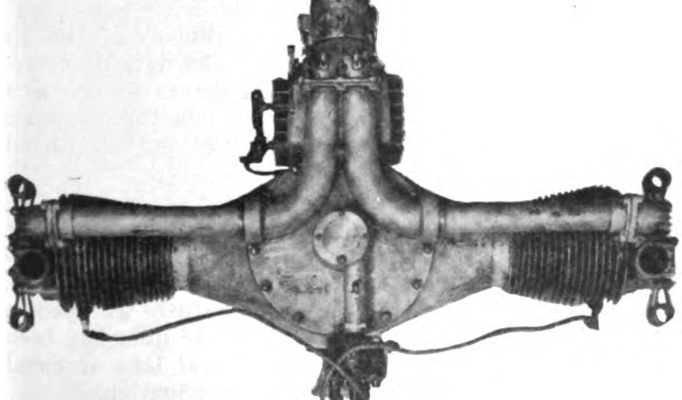
Since this type of control permits the maximum weight of charge to be supplied only when the mixture quality is such as to give a comparatively low power output per unit weight of charge, it is obvious that the greatest engine power will be slightly less than with types which permit the maximum power producing air fuel ratio to be obtained when the maximum weight of charge is supplied. This constitutes the chief limitation of this construction. That the marked advantages of this control appear only at full throttle can scarcely be considered a fault, as most commercial flying can be expected to take place under these conditions. An example of the variation of power that might be expected at different mixture ratios is given by the dotted lines of Fig. 3. Suppose the point O to indicate the desired mixture ratio for operation and hence the point at which the design permits the maximum charge to be supplied. The power at the other throttle positions has been estimated from the weight of air required to give the various mixture ratios and the indicated horsepower developed per pound of air at these mixture ratios as determined from the full line curves.



In the over-dimensioned engine, parts are designed for the stresses of full throttle operation at a certain altitude and the throttle closed so as not to exceed this power at lower altitudes. The mixture ratio control described above forms an admirable safeguard against full throttle operation at these altitudes, inasmuch as, under these conditions, it supplies a mixture too lean for engine operation. Moreover, some of the previously mentioned power loss at full throttle can be offset by an increase in compression ratio. A throttled engine can employ a higher ratio with safety than one operating at full throttle.

A Two-Cylinder Air-Cooled Aircraft Engine

FOR light sport planes the air cooled two-cylinder opposed engine seems to offer advantages. An engine of this type, rated at 40 hp. and weighing 128 lb., is being produced by the Aircraft Repair & Service Co. It has 4 x 6 in. cylinders cast of aluminum, with steel liners. Aluminum pistons with crowned heads are used. These are fitted with two rings at the top and a scraper ring below the piston pin. Large holes are drilled in the piston skirt to reduce its weight. The connecting rods are of H section, one straight and the other forked, hence the crank is of the single throw type and both pistons always move in the same direction. To minimize vibration, counterweights are secured to the crankshaft arms. The cylinder heads are detachable, and the valves, located in the heads, are operated by individual adjustable rocker arms.



A two-cylinder opposed aircraft engine

The lubricating system is of the dry sump type, all excess oil returning to an oil sump which is provided with cooling flanges. Oil is pumped to all bearings by a gear pump, a constant pressure being maintained.

The carburetor is a Zenith and ignition is by a Philbrin battery system. To prevent chilling of the incoming charge by the slip stream, the inlet manifold is located back of the engine. A ball thrust bearing is provided to take up the propeller thrust. The over all length of the engine, inclusive of the propeller hub, is 25½ in.; the width over the rocker arms, 42 in.; the height, 25 in., and the distance between supporting arms, 19 in.

ACCORDING to the present outlook, motor car manufacturers in France will have little business until trade generally is on its way toward recovery. Meanwhile firms are finding it difficult to tide over the crisis. Some are drifting into new fields; one is making machinery for contractors and marine work, another is hoping to secure a Government order for gasoline locomotives.

Automatic Control Employed in Spring Production

Lost motion has been very nearly eliminated in the manufacture of springs by a prominent Detroit company. Automatic recording pyrometers control electrically the thermostat on the gas burners of the furnaces. In other phases of spring production, also, mechanical devices have replaced skilled workmen to a large extent.

By J. Edward Schipper

AUTOMOBILE spring manufacture has been placed on a production basis with automatic control and the opportunity for error through the human equation has been reduced to a minimum by the Detroit Steel Products Co. Recently, the entire plant was overhauled and additions completed which introduce highly advanced methods and far greater efficiency into this branch of manufacture. With the additions, the plant now has a capacity of more than 6,000,000 lb. of springs each month.

All varieties of chassis springs are manufactured, including those for the heaviest motor trucks and trailers, as well as lighter springs for passenger cars, but so flexible is the arrangement of the production equipment that small orders or large tonnages, calling for long runs, can be produced with equal efficiency and economy.

The uninterrupted flow of this large variety of material through the plant has been accomplished by methods and devices so arranged that from the storage bins of raw material to the final inspection there is practically no lost motion. Specially designed equipment, largely the product of the company's engineers, plays a large part in maintaining this unusual output.

The routing of the steel through the plant is, in general, a series of continuous steps in each of the shop units. Interruption of production has been guarded against by the installation of duplicate machines throughout that can be put into service when the emergency arises. So far has this plan been carried that even two costly conveyor tempering furnaces have been installed and held in reserve, ready to be switched into the production line when needed.

The speed of production in this plant is based entirely upon the output of the furnaces. The dimensions and composition of the steel plates regulates the speed at which the furnaces are operated. When thin light plates are passing through the heat chambers, the speed is increased, and when plates of greater thickness and weight are treated, it is decreased. The tonnage of the shop will remain approximately the same, of course, whether large or small plates are being run, since a greater number of small plates will pass through the furnace in a given time.

Spring quality is based upon the heat treatment of steel. The furnaces, which are the latest type of automatically controlled, gas-fired type, were built by the McCann Harrison Co. Gas has replaced oil as a fuel because it causes less oxidization and scaling of the steel as it passes through the furnaces. Moreover, the temperature is much more easily controlled with the gas flame, and there is no carbonizing of the burners as was the case when oil fuel was used.

Automatic recording pyrometers electrically control the thermostats on the gas burners of the furnaces. So accurate are these controls that the heat is held within five degrees of the required temperature. Each of these instruments is locked in a glass case near the furnaces and the thermostatic controls are so guarded that workmen in the shop cannot tamper with them. Each pyrometer furnishes a permanent record of the performance of the furnace which gives the metallurgists and chemists a basis on which to make tests and experiments.

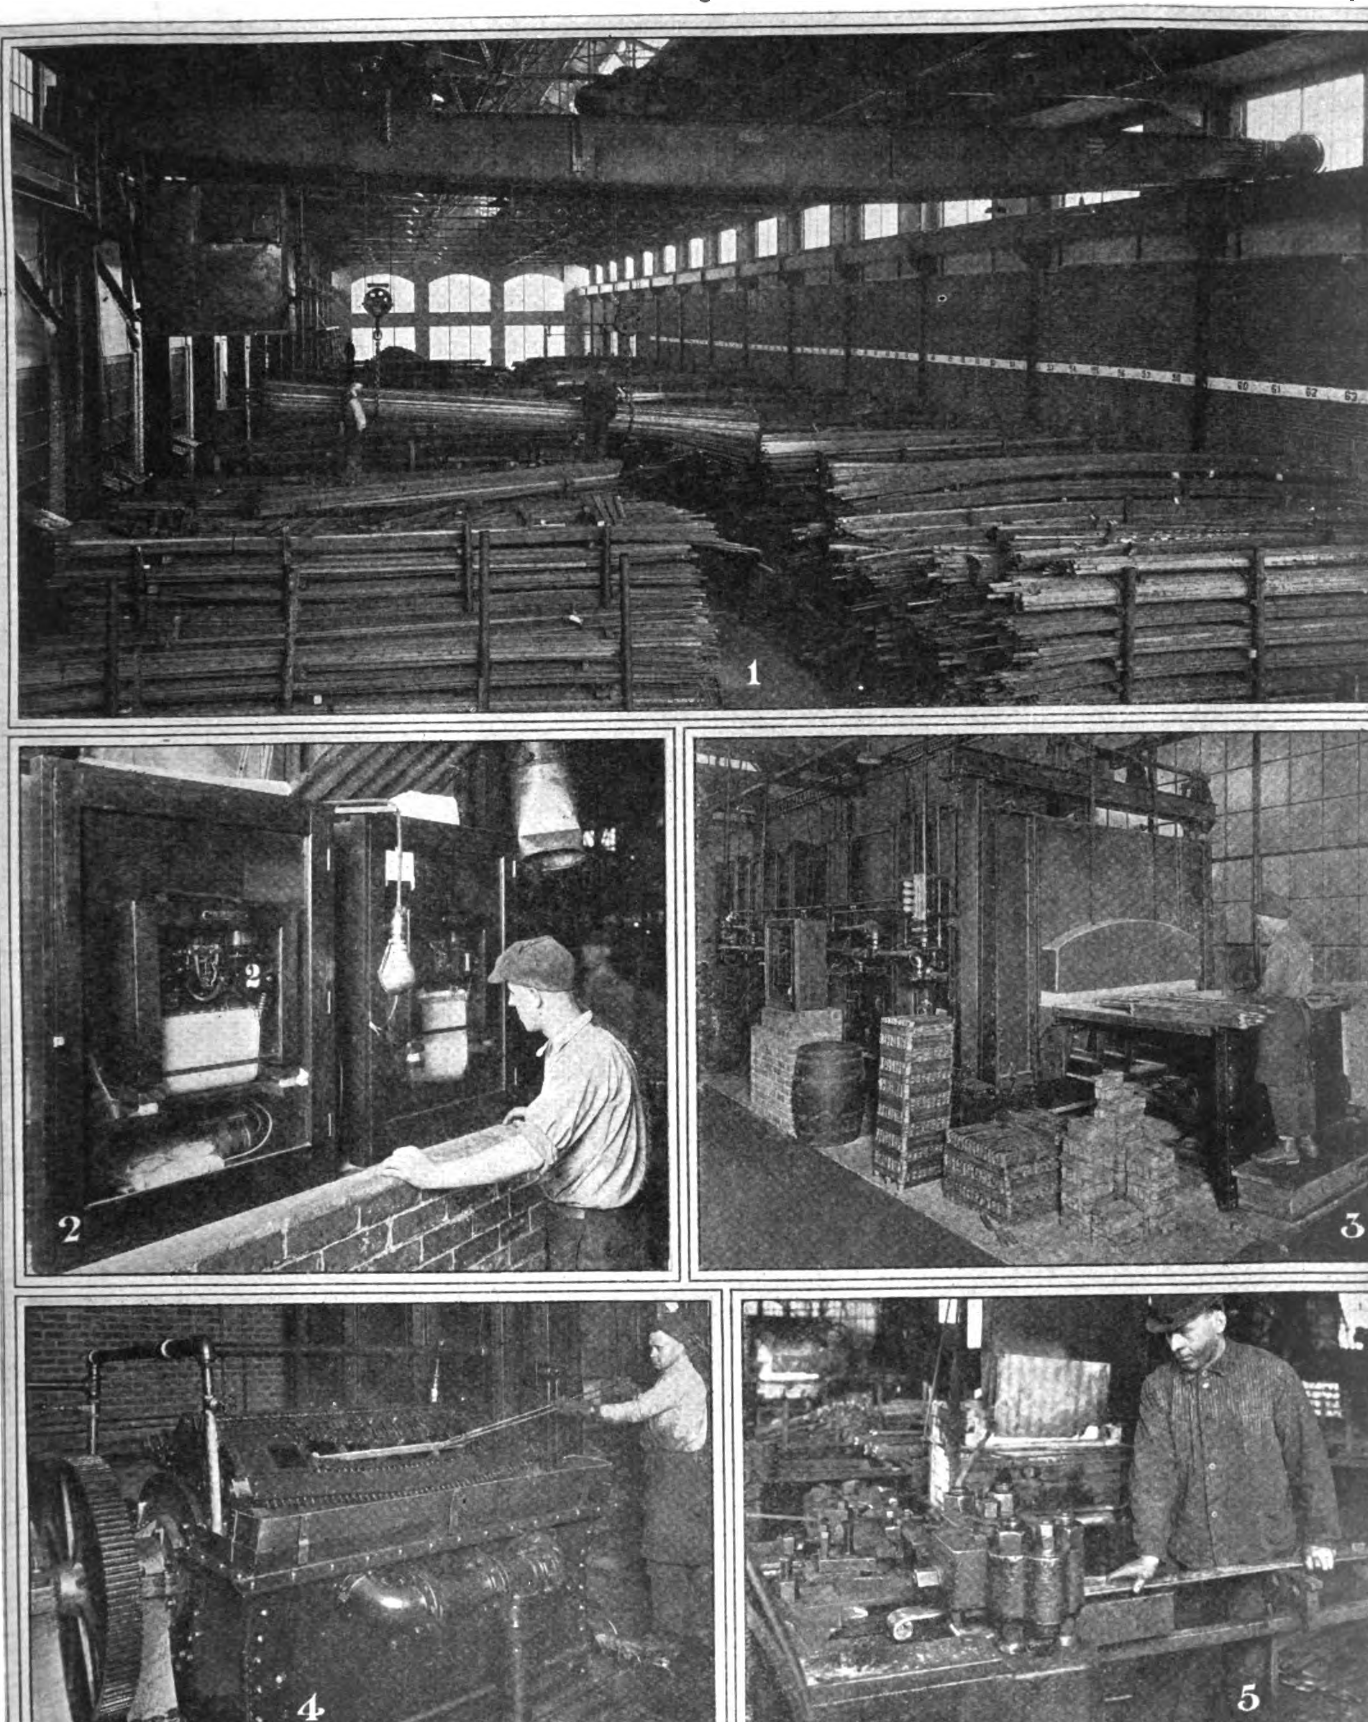
Before the automatic controls were perfected, it was necessary to depend upon the skill and judgment of the individual workman. The temperature at which the furnaces were operated was more or less a matter of guess work. A large corps of skilled operators was necessary to continually make adjustments on the burners in order that an approximately uniform heat might be maintained. To-day, human skill and judgment with their chance of error has been practically done away with, and the experience of the workman has little or nothing to do with the tempering of the steel in this plant.

Every lot of steel, even before it is removed from the railway cars, is subjected to tests by the metallurgists and chemists. Frequently, samples are tested along the production line. The photo microscope is constantly used to reveal the physical structure and character of the metal in the various stages of manufacture.

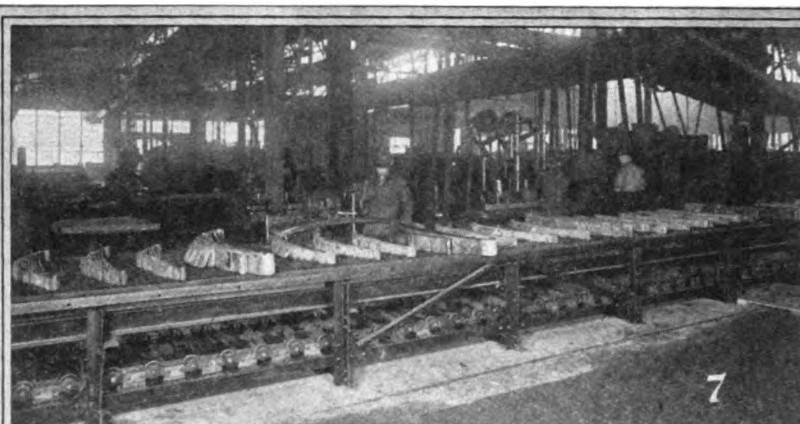
Figures and statistics given out concerning the steel are based entirely upon shop production, and not upon those compiled under ideal conditions by different societies and organizations. This feature is unique in that it tells the absolute facts about the springs. On the short leaf of each spring is stamped the date of manufacture and the key number which refers to the heat treatment. In case of trouble, this enables the engineers and metallurgists to make an accurate and intelligent analysis.

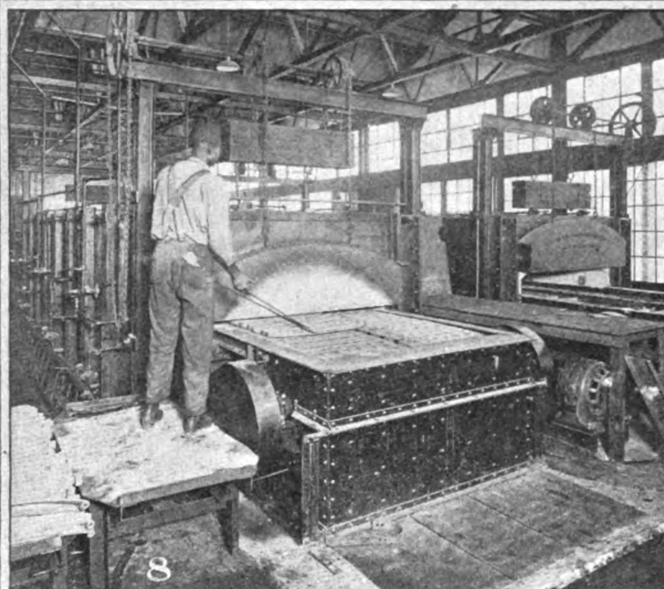
Proceeding with the first step in spring making, the long strips of steel are taken from the storage bins by the traveling crane and deposited directly upon the shearing tables where they are cut to the desired lengths. The varying length of the bars is carefully watched so that there is a minimum of waste. This item has been so closely figured that the present total loss of metal is less than 5 per cent for the entire production.

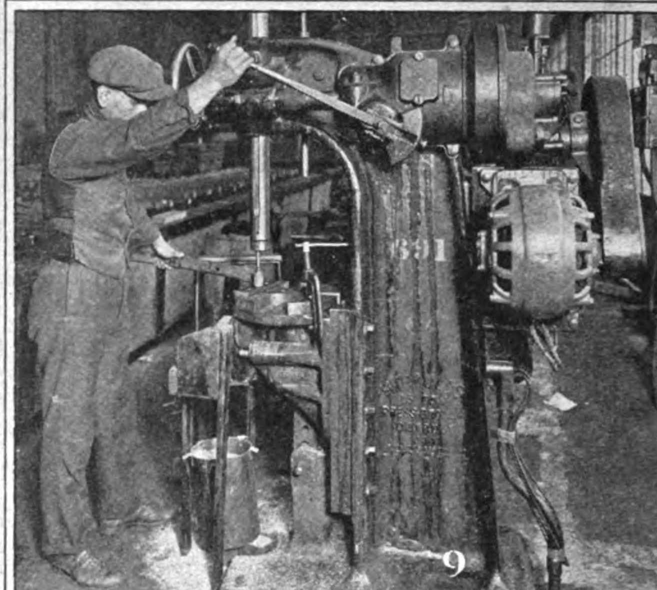
From the shears, the plates from which the main

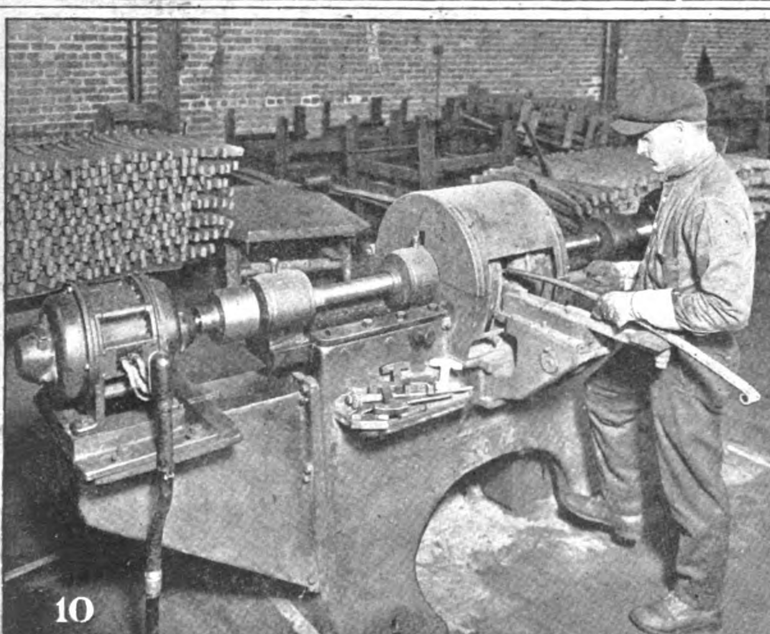


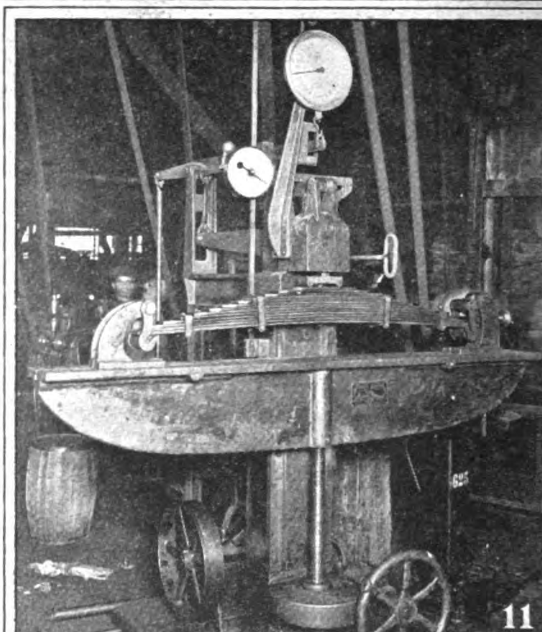
1—*The 20,000 tons of spring steel are carried in storage bins.* 2—*Electric controlling pyrometers are locked in glass cases and guard the constancy of the temperatures of the furnaces.* 3—*The McCann-Harrison walking beam type, gas fired tempering furnace. The output of these tempering furnaces controls the speed of production of the plant.* 4—*This machine, designed by the plant engineers, is new in the spring industry; it forms the camber in the spring leaves and tempers the leaves in an oil bath.* 5—*The McKenzie three-operation eye machine. First, the end of the white-hot plate is "shaved" and bent; second, the loop of the eye is made; third, the entire plate is aligned by means of special gages*











6—Complete sets of spring leaves are placed on the farther end of this conveyor table. When the spring is taken off the table it is ready for shipment. 7—The conveyor assembly table. It will be noted that four distinct types of springs are being assembled at the same time. 8—The "Draw-Fire." This is the McCann-Harrison low temperature furnace where the temper in the leaves is "drawn." 9—Hercules arbor broaching machine that broaches the bushings in the eyes of the main plate of the spring. This machine is of special design to meet the requirements of a single operation. 10—Facing machine which grinds the face of the eyes where they will be attached to the shackle bolts of the motor vehicle. 11—Olsen capacity machine by which the finished spring gets a thorough test

leaves are to be made are carried on small trucks to the forges where the ends are heated before passing through the "three-operation" eye machine. The red hot plates are placed in the machine and first the ends are scarfed and bent; second, the loop of the eyes are formed; third, the entire plate is aligned. This last operation assures the center line of the eyes being at right angles to the center line of the plate and parallel to its flat surface.

During this time, the other spring plates are sent to the punch presses where the ends are cut to the "diamond point" and the center bolt and clip bolt holes are punched. Trimming spring plates to the "diamond point" is rapidly replacing the old tapering process in which the metal was rolled thin at the ends. Engineers throughout the automotive industry favor this change.

The plates are now sent to the automatic gas fired furnaces. These furnaces are the walking beam type. The steel plates are laid on the bed of the furnace, and at regular intervals, three beams which run the entire length of the furnace raise the plates from the tile bed. By a cam mechanism, the beams then move forward a few inches, carrying the plates, and then lower them again to the bed. This process is continuous and every complete movement of the beams advances the entire contents of the furnace. Like all others in the plant, these tempering furnaces are controlled by the automatic pyrometer system, and do not require the attention of skilled operators.

Emerging from the tempering furnace, each glowing plate is immediately placed between the laminated teeth-like jaws of the forming machine. The operator closes the jaws and the plate is bent to the required camber and firmly held. The head of the machine then revolves and the plate is plunged into an oil bath and the temper is set. A moving steel conveyor belt carries the plates from the bath. A pumping system keeps the tempered oil in constant circulation, the hot fluid being piped to a cooling tower and the cool oil returned to the tank.

This machine is the product of the company's designers and embodies the qualities of speed and accuracy. With every complete revolution of the head, the spring is formed, with such precision that scarcely any adjustment is necessary. This is one of the greatest labor saving devices in the plant. Before this machine was perfected, it was necessary to employ a large force of workmen to make adjustments and fit the several plates in the spring. By this new process, the plates are made uniform and interchangeable.

All leaves which have passed through the forming machine are now placed in the low temperature automatic conveyor furnace. Here the temper is "drawn"; that is, the brittleness is taken out of the steel and it acquires the properties of elasticity and toughness. Here again the necessity for human judgment has been eliminated by use of the automatic pyrometer system.

After cooling to atmospheric temperature, the leaves are gathered in sets as they will be assembled and placed on the conveyor assembly table. The entire length of the table, on both sides, is flanked with machines, each operated by a single workman.

First, the bushings are pressed into the eyes of the main leaf by means of an arbor press of special design. This machine is so adjusted that when the bushing is flushed with the flat surface of the eye, the pressure is released. All the plates are rough polished on the bearing surfaces. Farther down the table, the bushings are broached to within one-thousandth of an inch of the specified dimension. The ends of the main leaves are faced in a special grinding machine with parallel wheels which are simultaneously pressed against the sides of the plates.

After this operation has been completed, the rebound clips are riveted to the leaves and the graphite lubricant is applied. The complete set of leaves is now pressed together in the "bolting-up" machine and the center bolt is fastened. The clip bolts are put in place and the nuts are riveted.

So efficient is the assembly plan that as many as five different springs can be assembled on the moving table at the same time. This has been found feasible in view of the elaborate inspection system employed in all stages of assembly.

That the complete spring will "stand up" with a wide margin of safety must be known to an absolute certainty before the spring leaves the shop. Every spring is, therefore, passed through the capacity test machine. Here every spring is placed under a load twice as great as that which it will be required to bear when it goes on duty in the automobile or truck. Every spring must stand this test without showing any excess deflection or permanent "settling." The clips, the bolts, the eyes, in fact, every part of the spring is tested on this machine. Every detail is minutely inspected before it is finally O. K.'d for the customer. The springs are then sent directly to the loading platform where they are weighed and checked for shipment.

Diesel Type of Engine for Motor Vehicle Work

(Continued from page 501)

The ignition chamber is not jacketed but is provided with cooling flanges. In the illustration, E is the auxiliary fuel pump which delivers fuel to the auxiliary jet C through pipe D. It is a simple plunger pump operated by cam G and lever F. Below the camshaft is a small control shaft H with stop I. The main pump, which is not shown, is of the same type and driven in the same manner.

In regular operation the ignition chamber is at a high temperature. The engine is started cold by means of an air bottle which is filled, while the engine is in regular operation, with high pressure air from the engine cylinder. A period of 30 seconds is said to be sufficient for starting, and during this period sufficient fuel flows through the auxiliary jet C for operating the engine under its own power and heating up the ignition chamber. Then operation on the regular cycle begins. The Steinbeker engine is said to be as easily reversible as the regular Diesel engine, a feature which is of importance in marine work.

New English Aircraft Engine

WORD comes from England of a new Napier aircraft engine of over 1,000 hp. It is an X-type engine with 16 cylinders, designed by J. Rowledge, and is said to weigh not very much over 2 lbs. per horsepower. This would seem to indicate that British designers are going in for heavier, more substantial engines, because a specific weight of 2 lbs. per horsepower was very closely approached in the Liberty engine, which is 400 hp.

New Automatic Chucking Lathe Developed at New England Plant

The Hartness automatic chucking lathe is a new tool specially suited for turning up ring gears and similar parts. The tool carriages are mounted on cylindrical bars which slide in bushings at both ends of the frame.

By P. M. Heldt

A NEW tool specially suited for turning up such parts as automobile ring gears has been developed by the Jones & Lamson Machine Co. The objects in view in the design of this machine were to produce a chucking lathe that would eliminate errors from indexing and that would be of great rigidity, so as to permit very accurate work to be turned out and at the same time using high cutting speeds. As an indication of

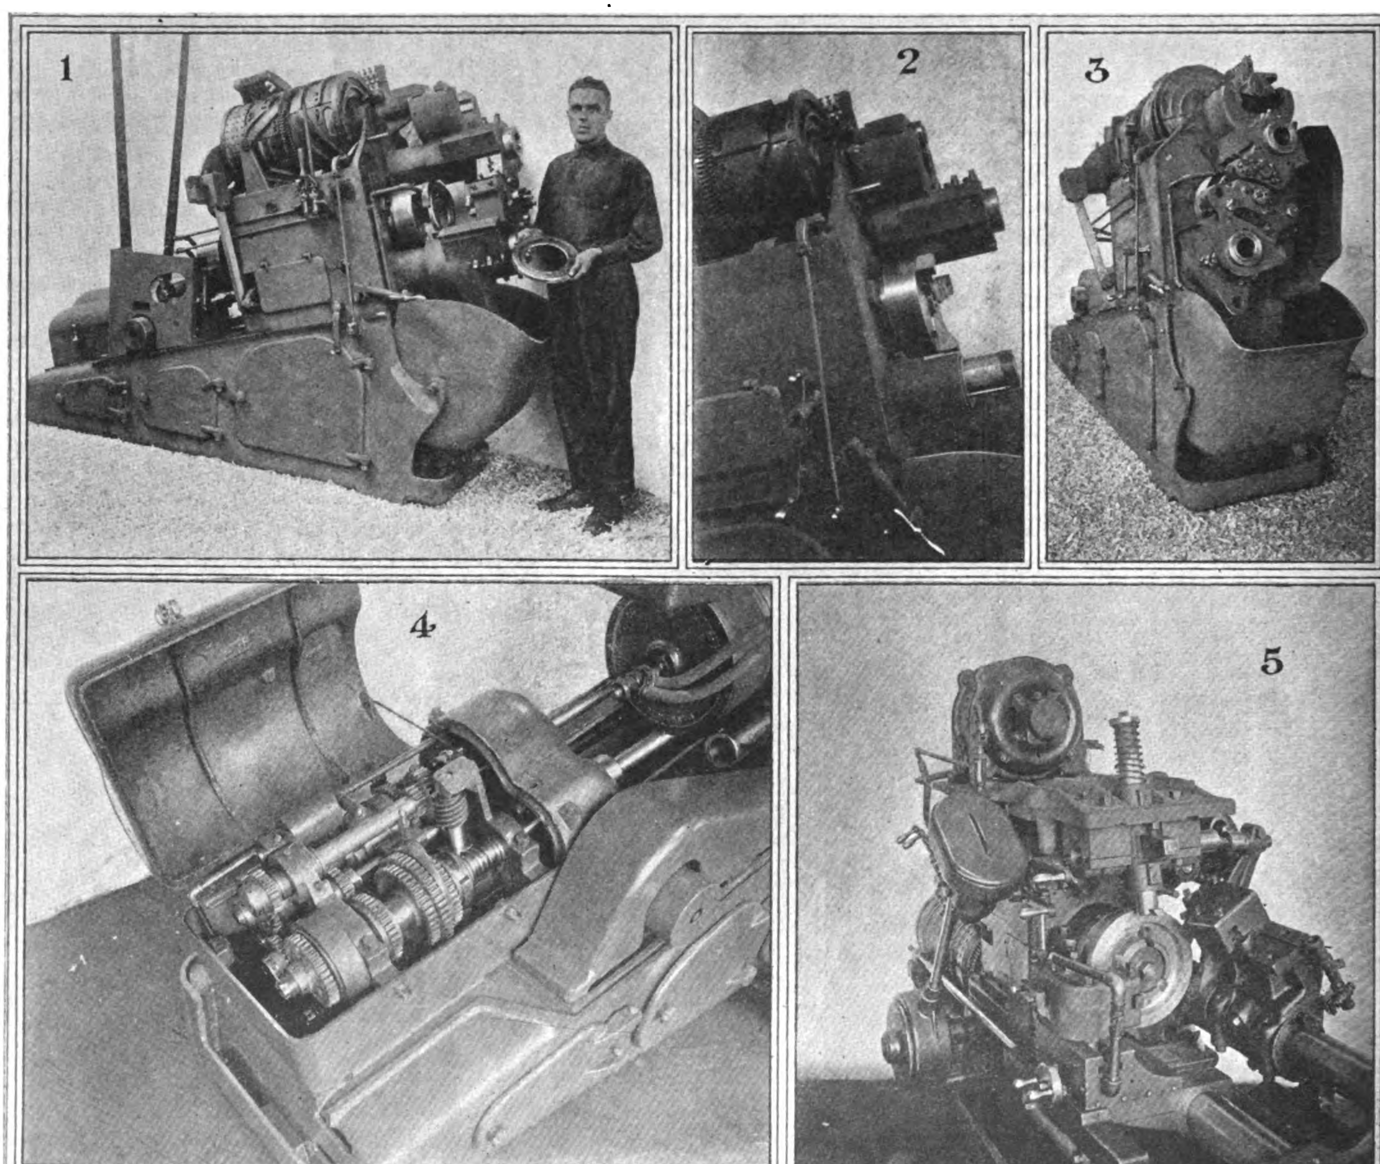


Fig. 1—Hartness automatic chucking lathe. Fig. 2—Showing chuck located between front bearings of tool head bars, so as to avoid overhang. Fig. 3—Front view of Hartness automatic chucking lathe with tool heads in place. Cross feed for facing cuts is obtained by giving an angular motion to lower tool head bar. Fig. 4—Change gears of Hartness lathe. Fig. 5—Second operation on ring gear blank, in Fay automatic lathe with pneumatic fixture

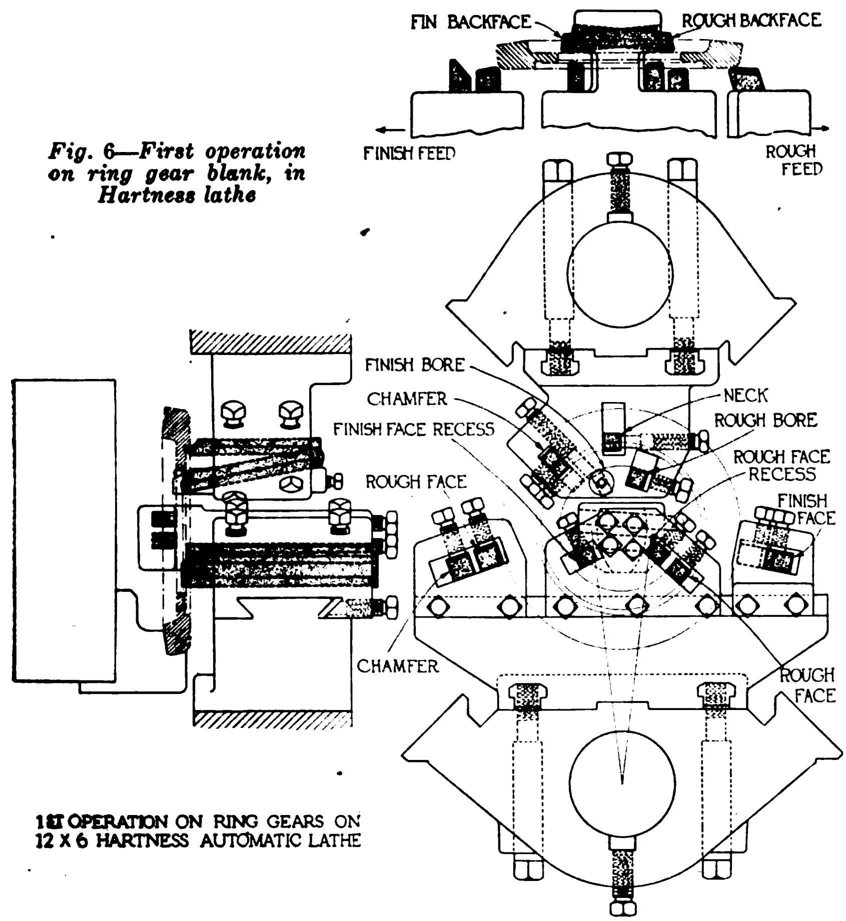

Fig. 6—First operation on ring gear blank, in Hartness lathe

what can be done on this machine in the way of rapid production, it is stated that on cast iron, cutting speeds of 125 ft. p.m. can be maintained on the roughing cut and 175 ft. p.m. on the finishing cut. It is not practicable to give cutting speeds for steel, because the hardness of the steel varies so much with the treatment it receives previous to machining.

The maximum dimensions of work that can be handled in this lathe are 12 in. in diameter and 6 in. in length. Operation of the machine is entirely automatic. All the operator has to do is to chuck and remove the work and to start the lathe after a piece is chucked. The regular equipment provides for eleven changes of speed, from 25 to 135 r.p.m. The feeds for the cutting tools are controlled by cams mounted on a large cam drum. This drum is driven by change gears for the feeding movements and is also driven at high speeds for idle movements. The clutches and gears are located in a separate box at the rear of the machine and are rendered accessible by lifting the cover. The gears are of steel and hardened.

The tool carriages are mounted on large cylindrical bars which slide in bushings at both ends of the frame. The front bearings are in large bosses cast integral with the frame and are directly in line with the cutting strains, thus avoiding overhang. The upper tool carriage bears the tools for boring and turning cuts; it has an axial motion of 7 in. and can also be slightly oscillated so as to bring first the roughing and then the finishing cutters into operation. On the lower tool carriage are the tools for all facing cuts; this too has an axial movement of 7 in. and will face any distance up to 3 5/16 in. when the cutter is on center.

The work spindle is 4½ in. in diameter and has a 3⅝ in. hole; it has the face plate forged integral with it. The machine is adapted for electric motor drive, and when this drive is used, the motor is mounted in the base. Change gears not in use are carried on a door of the base.

Although the lathe is adapted for quite a variety of work in the automotive line, its advantages stand out particularly in connection with the boring and facing of ring gear blanks. The blanks are held in the lathe by means of a three-jaw air chuck. The first operation consists in rough-boring the hole, which is done with a forged tool. As soon as the rough-boring is completed, the finish-boring cut begins, an inserted tool being used for this cut. These two tools are carried by the upper tool-head.

The lower tool-head carries eight tools, four for rough facing, one for chamfering and three for finish facing. Two cutters are used for rough facing the back face of the gear ring, one starting from the outside and the other at the same time from the inside, or from the hold. The third roughing tool roughs out the recess and the fourth the inner face of the ring flange. These four tools therefore rough three surfaces and all of these surfaces are finished on the return motion of the tool-head. As the feed of the tool-head reverses, the spindle speed is automatically increased so as to provide greater cutting speed during the finish cut. The machining time on such ring gears varies from three to six minutes, according to size, amount of stock to be removed and hardness of metal. The ring gear of a popular make of six-cylinder car, which measures 10¾ in. in diameter, can be put through this operation at the rate of twenty per hour.

From the above outline of the operation on the Hartness lathe it will be seen that only the boring and the facing of surfaces perpendicular to the axis are accomplished in this machine. The remaining surfaces, that is, the face and both ends of the toothed portion of the ring, are machined in the Fay automatic lathe, a number of chamfering and rounding cuts being taken at the same time. The ring gear is again held in the lathe by means of an air-operated fixture, this time with the

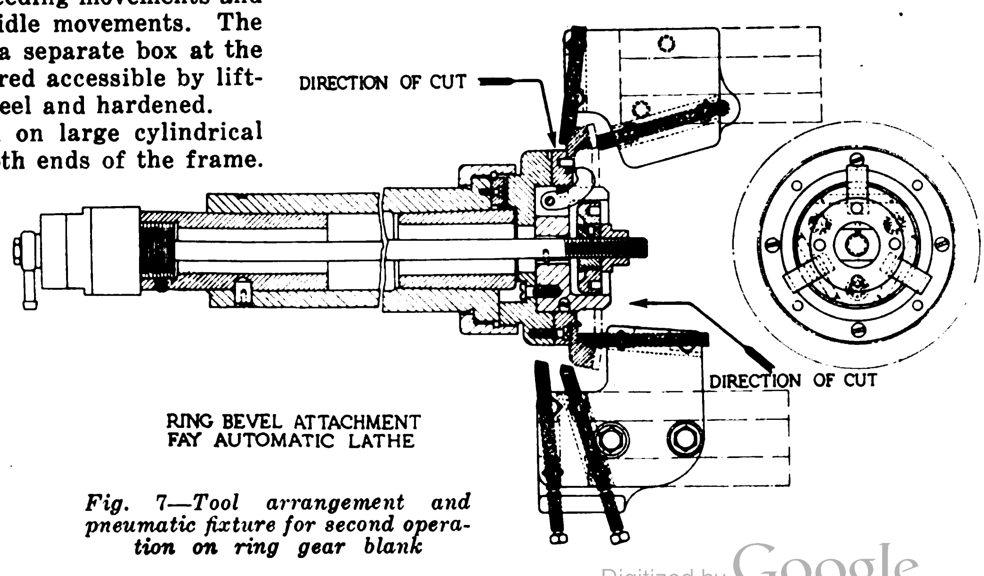

Fig. 7—Tool arrangement and pneumatic fixture for second operation on ring gear blank

toothed side away from the chuck, as shown in the illustration (Fig. 7). It is located either by the bored hole or the counterbore finished in the previous operation, and is held against the back face by pawls or fingers which grip on the surface that was back-faced in the first operation on the Hartness lathe. The work done on the Fay lathe consists in roughing and finishing the outside and the face angle and boring the inner edge of the teeth. The tool arrangement is shown in Fig. 7. One tool roughs the outside and another finishes this surface after the first tool is across. The same carriage which carries these tools also has a tool for boring the inner edge of the teeth; it finishes this surface in one cut from the rough and starts cutting immediately the turning of the outside has been completed. The long face angle is rough-faced by a tool mounted on the back arm and is finish-faced by a tool mounted in the overhead slide (see Fig. 5). The back arm also carries a tool for turning the radius at the back of the gear. Owing to the rigidity of the machine, the degree of accuracy demanded in automobile ring gears is secured even though roughing and finishing cuts are taken at the same time. Taking roughing and finishing cuts simultaneously of course greatly increases the rate of production. All the operations described can be performed in practically the same time it takes for a roughing cut across the long front face, and the largest sizes of automobile ring gears are put through at the rate of 12 to 15 per hour.

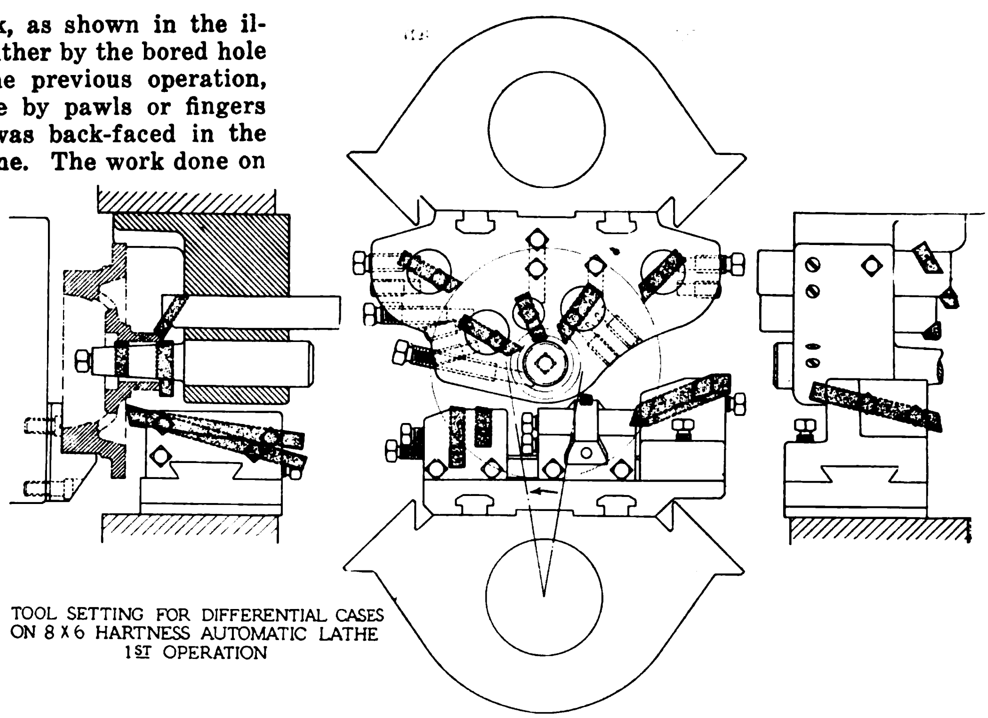

Fig. 9—Tool arrangement for machining outside of differential case in Hartness lathe

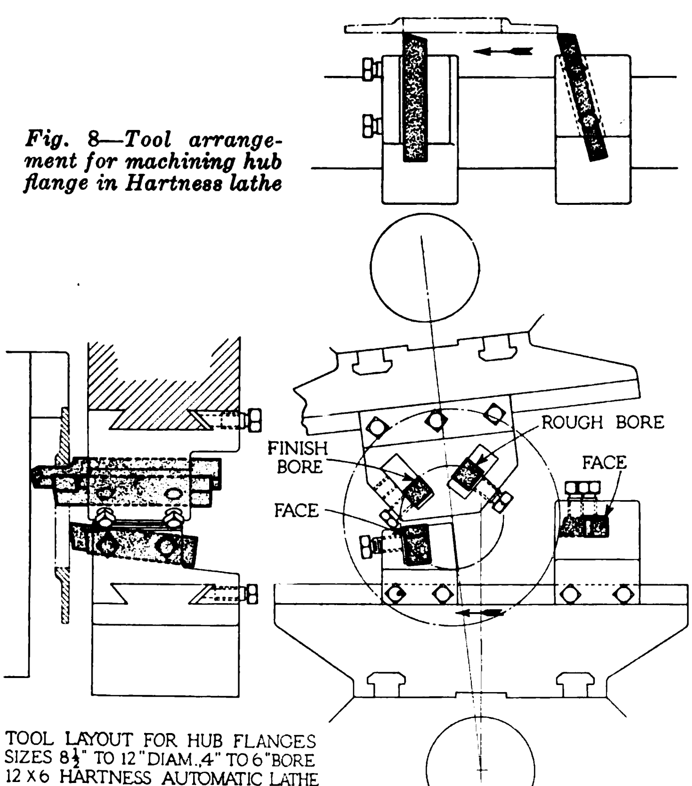
Fig. 5 shows one of these ring gears held in position by an air-operated fixture of the type shown in detail in Fig. 7. Hand-operated devices are sometimes used for holding the rings, but are, of course, slower. The advantage of the Fay automatic lathe for this work lies in the fact that in addition to taking all of the cuts at the same time, the machine goes through all its motions automatically, the only work the operator has to do being to put the work into the machine and pulling down the starting lever. One man runs two machines on practically all work, and the idle work of the machine is very slight. The direction of motion of both carriage and back arm is controlled by the proper setting for formers and cams.

Fig. 8—Tool arrangement for machining hub flange in Hartness lathe



Another piece of work in the automotive line that can be done to advantage on the new Hartness automatic lathe is the turning of hub flanges. This is illustrated in Fig. 8. Two tools carried by the upper tool-head rough and finish bore the hole and two tools carried by the lower tool-head face the inner side, starting from the outer and inner edges simultaneously. Roller bearing outer races of large diameter can also be handled in this lathe. The race or ring is held in swivel jaws so that it is gripped at six equi-distant points on its circumference and distortion due to the clamping pressure is held down to a minimum. The upper tool-head carries a taper slide which bores the taper hole. The lower tool-head carries the cutters for facing the front and back faces and for chamfering the corners. In the next operation the piece is held on a taper arbor by air pressure. The upper tool-head first rough-turns the outside and then swings slightly to bring the finishing cutter into position and feeds away from the chuck on the finishing cut. Cutters for rounding both outside corners are carried by the lower tool-head.

Another operation to which the machine is adapted is the machining of differential casings (see Fig. 9). In the first or outside operation the flange is rough and finish-turned, the hub turned (two cuts), the flange faced, the hub faced and the hole bored. How the work is divided between tools carried by the upper and lower tool-head may be seen from the illustration.

The differential gear is a part that does not vary much on different cars, and its housing is ordinarily a difficult part to machine, owing to the many surfaces to be finished. Lay-out here shown makes this a simple operation.

The True Function of an Employees' Lunch Room

It doesn't cost anything to think, and an excellent opportunity for making plans is presented when production does not demand intensive effort for the time being. The real function of the employees' cafeteria is not always determined beforehand. The subject is worth serious consideration.

By Norman G. Shidle

A SUMMER visitor to a rural town became interested in an old rustic who seemed to spend his entire existence sitting on the cracker barrel at the village store. Finally the visitor approached the native one day and asked curiously:

"What do you do here all day long?"

"Well," the old man replied, "mostly I sit and think; sometimes I just sit."

When sales slump off and the intensive drive for production has temporarily become unnecessary, an excellent opportunity is presented to sit and think—and a dangerous opportunity to "just sit." While the present time may not be favorable to the development of new phases of manufacturing efficiency, it is very favorable for considering carefully the lines along which such developments should go, for determining how weak points in the organization may be strengthened and how former mistakes and deficiencies may be corrected.

The function of the factory lunch room or cafeteria, its usefulness and its relative production importance is one factor which may well be considered during these days when there is time to "sit and think."

The employees' lunch room has ancestors a few generations back which often cause its real function to be mistaken. One of those ancestors was the hot coffee and doughnuts which comprised the beginning of "welfare work." This ancestor proved to be a fraud in many cases, acting chiefly as a substitute for fair wages and decent working conditions. Those days, of course, are long since passed. The philanthropic ideals which dominated even the most honestly conceived "welfare work" are no longer being considered with favor.

And the factory cafeteria or lunch room is shaking itself free from the unfortunate association with its "philanthropic" ancestors.

That association is rightly called unfortunate, because the factory lunch room cannot attain its highest effectiveness either from the standpoint of the employer who installs it or of the employee who utilizes it unless conceived and operated on a self-respecting and businesslike basis.

In most modern industrial plants the employees' lunch room has a place. Some of the chief reasons for this are:

1. **Frequently there are not adequate eating accommodations adjacent to the plant. In many cases it would be impossible for the worker to get any lunch unless he carried it from home.**
2. **The luncheon hour should be a period of relaxation, if the man is to start his afternoon's work with renewed interest and energy. This is impossible if he must crowd himself into some small illy-ventilated lunch room, where neither the surroundings nor the atmosphere invite him to remain for a moment longer than is necessary to eat his food as rapidly as possible.**
3. **Nearly all public lunch rooms near to manufacturing plants are of this kind. Clean, inviting lunch rooms will not accept the patronage of men in dirty overalls and greasy clothes. Men do not eat in dirty lunch rooms from preference. Such eating places have a decidedly bad psychological as well as physical effect, the results of which accrue to production in the afternoon.**
4. **The cold lunch is often the only alternative to these public lunch rooms. The ill-effects of constant cold-lunch eating have been so widely and effectively discussed as to need no repetition here.**

Consequently, the employer gains a definite advantage from providing decent eating facilities for his employees. So well-known an authority as Daniel Bloomfield states that "to make such provision even at an immediate financial loss, involves no philanthropy." This is doubtless true, but there is really no reason to operate an employees' lunch room at a loss. While it would not be good policy for the employer to attempt to make his lunch room a source of profit, there is every reason for him to charge a fair price for the food served, so that the lunch room will pay for itself.

The object of the employees' lunch room is not to gain the men's good will by giving them a daily present, it is merely to provide them with the opportunity to buy at a fair price that comfort and nourishment for which they are willing and able to pay. We all like to get things as cheaply as possible, but we are better satisfied when we pay for them at a fair price than when they are given to us by someone for whom we are working.

When the lunch room is operated on a self-supporting basis there is no chance for suspicion to arise on the part of the workman that the employer is giving him something at noon hour and taking away twice as much during working hours. No employer does that to-day, of course, but facts are not necessary to arouse suspicion. Letting the workman pay his way leaves him with a feeling of independence and self-respect—and this feeling is the charm which wards off the ghosts of the cafeteria's ancestors. It is impossible to study human relationships in industry and not come to believing in ghosts; they are often very real.

The lunch room will do more than aid the digestion and physical well-being of the workers. It will, of course, do these things. The production advantages of such aid have been discussed and written about at great length—probably with too much enthusiasm at times. Nevertheless, it is certainly true that better work will come from employees who have an opportunity to eat a decent warm meal at noontime.

But the clean atmosphere and surroundings of a well-equipped cafeteria provide for the manual workmen that relaxation and opportunity for social intercourse which most executives enjoy so much. Office workers usually look to the noon hour as a time for "talking things over," for enjoying the company of their fellow workers and for having a pleasant relaxation from their work. They all eat, it is true, but the psychological features play fully as important a part as the physical appetite. We all know the effect it has on us. The clean, pleasant cafeteria has the same effect upon the manual workmen. Strangely enough, most of his reactions are just like ours.

Having determined that a well-conducted cafeteria is a benefit to all concerned, careful attention should be given to choosing and installing the proper equipment. To accomplish the objects in view, adequate service should be provided at the lowest possible cost—but the service must be adequate.

It is possible by means of a cafeteria system to serve a large number of people in a very short time, and such a system is often desirable in the employees' lunch room. An example of good service in this respect is to be found at the big cafeteria of the Westinghouse Electric Company. Although this installation is much larger than would be necessary in a majority of plants, its operation illustrates the best modern practice and has been adapted elsewhere on a smaller scale.

In this particular case an entire building is devoted to cafeteria purposes, the first floor being divided into separate sections for men and women. The second floor is one large cafeteria for both men and women.

The employees enter the building at the center and proceed up an incline or ramp to the second floor. Thence they go to the section of the cafeteria nearest them. After eating, they depart from the building at either end down other ramps. Thus there is a continuous circulation of employees in and out through different entrances. Some such system as this is desirable in any factory lunch room, as it eliminates crowding and confusion.

A belt conveyor has been installed here upon which the employee places his tray as he goes down the line selecting his food. He picks up his tray and silverware, as in an ordinary cafeteria, but instead of carrying or pushing it, he places it on this moving belt. Thus the tray moves along, the employee following it. This prevents the line being delayed, since all the food is laid out on the plates in advance and it is necessary simply to pick one up and place it on the tray as the tray moves along. This arrangement permits the serving of 34 persons a minute by each service counter.

Since this moving belt idea was an innovation, the employees were just a bit afraid of it at first. To overcome this difficulty, cafeteria attendants were stationed at each end of the line to shut off the belt motor in case a jam should develop. The employees quickly found that if the tray moved along a trifle too fast they could hold it in place on the belt while they were getting what they wanted.

After the employee has finished eating he picks up his tray and carries it to another moving belt by which the tray is carried to an automatic elevator, which in turn takes it to the dishwashing room. This belt conveyor system is one of the chief features of this particular installation. This Westinghouse installation was made by Albert Pick & Company and contains many other details of efficient cafeteria practice in connection with the preparation and serving of food, dishwashing, etc.

The best results in a special instance, however, can be obtained only by providing equipment especially adapted to the needs of the particular plant. The instance cited merely shows the advantages which can be gained from thorough study and planning. Excellent advice along these lines can usually be obtained from the companies which specialize in lunch room equipment and installations, and the manufacturer may as well take advantage of the service which these firms have built up for his benefit.

One phase of employees' restaurant operations that should not be overlooked is that which concerns the serving of food which will be in accord with the religious, as well as the physical attributes of those who are to consume it. The menu should always be so arranged that there will be sufficient variety to give a full meal to every man every day regardless of his religious affiliation. There should never be a day, for instance, when pork is the only meat served, nor should fish of some kind be omitted from the Friday bill-of-fare. In a plant which employs a large number of foreign workers, the menu should be such as to allow for the various fast days or religious observances of the different groups.

In plants where there is any kind of employee association, it is well for a restaurant committee to be appointed from that group.

In smaller plants, a regular lunch room with waitresses and table service has often been found to be effective. In any case, the eating place and its service should embody the following essentials:

1. **Cleanliness.**
2. **Fresh air and good light.**
3. **Rapid service.**
4. **Good food at cost price.**
5. **An orderly method of entering and leaving the eating place.**
6. **As much quiet as is consistent with efficient service.**

Many times the company lunch room is as desirous from the standpoint of office workers and executives as from the standpoint of the workmen in the shop. In such cases, one of two plans may be followed out:

1. A separate space may be provided for this class of employees.
2. Both executives and workers may eat in the same place.

The first plan is the one most generally followed and has much to commend it. In certain other cases, however, the second system is successful. There is much to be said in favor of the latter system, especially from the standpoint of "democracy," but the best results will probably be obtained in any individual case by doing what the executives honestly feel to be the best in that instance.

It should be noted, however, that eating in a clean place alongside of clean people is likely to make the workmen in general more cleanly in their habits. A well-known machine tool plant in New England about a year ago installed a lunch room for its 500 employees. In this lunch room a regular lunch is served at a fixed price, the food being served to the men by waitresses.

Executives and workmen eat at the same table side by

side. Conversation is perfectly natural, the executives simply act as nature prompts them to act, and there is no resulting loss of dignity; nor is there evidenced any of the false enthusiasm or feigned "good-fellowship" which goes with excessive or forced geniality.

In this instance the personal cleanliness of the workers at lunch-hour is very noticeable. Men in very dirty, greasy working clothes come in to lunch with their hands and face thoroughly washed and cleaned. This is true of almost every workman who eats there. Whatever might be the result elsewhere, this condition has come about naturally in this plant, since no effort was made by the management to bring it about.

The president of this company happens to have a very exceptional understanding of human relationships and is one of those perfect gentlemen with whom anyone feels entirely at ease. The executives with whom he has surrounded himself are of the same type. This accounts to a large extent for the success of this "democratic" method of running the lunch room. These men really seem to enjoy eating with the workmen and to be better contented than if they had a separate dining room to themselves.

In many other cases, however, such a plan might be unpleasant for both employees and executives. Nothing is to be gained from attempting to force executives to be what they are not; to eat among workmen as a matter of policy rather than as one of desire. And it must be recognized, of course, that workmen in various plants differ greatly. Moreover, executives often desire to utilize the lunch hour for business conferences, and thus require a segregated eating place.

Whether or not the office employees' lunch room should be segregated from that of the shop employees is one to be decided chiefly in accordance with the feelings of the executives in charge of the plant.

It is not often that the publicity material of a company with goods to sell can be quoted as reliable information about that product. A good summary of the requirements of a successful factory cafeteria, however, is contained in a booklet recently issued by Albert Pick & Co., and comprises an excellent summary to this discussion.

"Whether a cafeteria pays or is run at a loss depends upon its mode of operation. It has to be carefully planned and properly conducted. It is an important business venture which will run away with itself in expense or fall behind in service if it is not well equipped. It is a restaurant and should be conducted on restaurant principles. It should not be entrusted to the tender mercies of novices or theorists. An expert restaurant man or woman should be placed in charge. The food should be purchased in quantities. A careful check-up system should be provided. There should be sufficient variety. Prices should be based on cost. Waste should be eliminated and the most stringent food conservation policies used. * * *

"Whether the factory be great or small a thoroughly thought-out plan can be put into operation in the way that will meet its requirements best."

Let Everybody In

DISCUSSING what he believed to be the ineffectiveness of certain forms of "welfare" work as carried on in his plant, the vice-president of a large New Jersey automotive concern said recently:

"Take, for example, our baseball team. The team is very successful and wins a large percentage of its games. We employ, however, a large number of foreign-born workmen, many of whom scarcely speak English. These men are not at all interested in baseball and never attend the games. They do not understand it and have no enthusiasm for it.

"So it is with many of the other employee activities which we carry on. These foreigners, who comprise a majority of our employees, are entirely out of them."

This executive brings up an important point which is not often recognized in the organization and operation of employees' service work. The tendency is to organize and promote activities which the personnel director is familiar with and which, as Americans, we feel the foreigner ought to take part in.

A particularly good analysis of this special problem is given by Daniel Bloomfield in his recent book, "Labor Maintenance." Bloomfield says in part:

"It is often noticeable that games, like languages, are something that need to be acquired, and the methods of acquiring them have to be planned with intelligence. The teacher of English does not start by ridiculing the mother tongue of the alien who is to be taught. In the recreation room and on the playground the same tact needs to be employed. Plays and exercises traditional with the alien have often been subjected to disheartening ridicule, with the result of driving him away from play activities.

"He gets the burnt-finger attitude. Such disaffection is a loss to the organization and a handicap to right relations. The alien is sensitive about his customs and native mode of self-expression, as we should be in the same situation. Wise recreation leadership will see to it that not only does each member of the organization find a place in the activities going forward, but can do so without loss of self-respect or danger of humiliation."

Better Road Construction

THE need for improved roads and a lower cost of operation is becoming more and more apparent. Railroad congestion, brought about by the necessities of war and government control, with the resulting increased use of motor trucks, has made the highway problem a serious one. While intermittent attempts have been made to establish an efficient highway system in the United States, yet it has not been possible until recently for the automotive engineers to meet with the road experts and work out a definite engineering plan of re-establishment and improvement. Many organizations have been at work during the past year on this important problem. Thousands of experiments have been made by government experts, automotive engineers and road builders. Their investigations have revealed startling facts. Borings to a depth of 10 to 15 ft. below the road surface have shown that many of the roads recently constructed are built on an entirely wrong plan. As one engineer expressed it: "You can't lay a road like a carpet over sand and expect it to last, but if you build it like a bridge, it will." The subsoil several feet below the actual bed of the road has been found to have a very important bearing on the lasting qualities of the highway. Many of the pet theories of experienced road builders have been totally exploded, and new methods which on their face looked fanciful have been found to possess real merit.

Road Construction to Build Up the Exports of Automobiles

This is a discussion of the work which should be done by exporters in furthering highway improvements in Latin-America, South Africa, Australia and China, with comments upon the value of graded dirt roads in these developing territories rather than hard-surfaced construction.

By George E. Quisenberry*

TOO little attention has been given by automotive exporters to the furtherance of road and highway improvement work in the foreign field. This statement is readily proved by even the slightest study of road conditions throughout such great stretches of territory as Latin-America, South Africa, Australia, and China where America must look in great measure for the future absorption of the cars, trucks, tractors and equipment it ships into the export markets.

These territories to-day are awake with the idea of road building as they never have been before. In the last few years, they have bought motor cars by the thousands and this has brought about a consciousness of the need for highway improvement that no other agency could have aroused. But the interest—and only here and there has it yet been fused into the actual construction of many miles of good roads—must be quickened so that future expansion may assure the automobile its rightful place in the transportation systems of these growing and developing countries.

In a word, the automotive exporter must get behind the idea of good roads, he must push their construction and, in large measure, he must supply the impetus and the propaganda necessary to transform thought into action. He can do nothing else that will have such a lasting effect upon the industry he represents and be such a potent factor for its rightful development through the coming years.

Let us look at the situation as it exists to-day, taking Latin-America as the example. This is a territory comparatively sparsely settled and devoted almost entirely to agriculture. Great stretches of the Argentine, Uruguay and Southern Brazil, as well as the inland valley of Chile, present no difficulties to the opening up of serviceable highways. Being agricultural, the problems of road development become analagous to those of the farming districts of our own Middle West.

The Argentine is almost as level as a man's hand over three-quarters of its wide expanse. Land has been cheap and broad national highway routes have been laid out in nearly all of the more prosperous territories. Their width, to one who has been used to the roads of this country or Europe, is well nigh astounding, being 80 to 100 ft. or more. Their development has been left to nature and the huge two-wheeled carts of which the automotive exporters have heard so much. The result has been the natural one that such highways are often impassable and that long distance touring is attended with perplexing difficulties.

Managing Editor, El Automóvil Americano.

The testimony of a recent traveler, representing an American tire maker, who traveled all over the Argentine in an American automobile, is illuminating.

"Good dirt roads for light traffic are not difficult to build here," he says. "It was noticeable on the road from Buenos Aires to Cordoba that wherever there was ditching and even a small amount of grading, there was no trouble in passing. What work was done, however, was done with the pick and shovel. Road machines, which might clear up a dirt road very quickly, have not penetrated to the Argentine. If motor owners and those in the sale of motors and road machinery makers would get together, they could do much to get the work of road making under way."

Road builders agree that the problems of highway building are centered in overcoming water and frost. In other words, drainage and freezing weather. For the Argentine, the latter may be forgotten, as it may for most of those parts of Latin-America which concern the exporter of automotive equipment.

Get rid of the water and the good road has become a reality. Apply this to the Argentine, to Uruguay, to Brazil, to Mexico, to interior Chile, and see what the result will be in future expansion of the motor car.

The proper construction for these countries is that known as the graded dirt road. The roadway is graded above the water, ditched for proper drainage, and crowned so that rain will quickly run off to the sides. This is the same road, easily and quickly built and with slight expense, that carries the great traffic in motor cars through Missouri, Kansas, Nebraska, Illinois, Ohio and the other grain growing states. They are constructed with a small amount of mechanical equipment, present almost no engineering problems and can be maintained with the home-made drag. Furthermore, they are almost year-around roads.

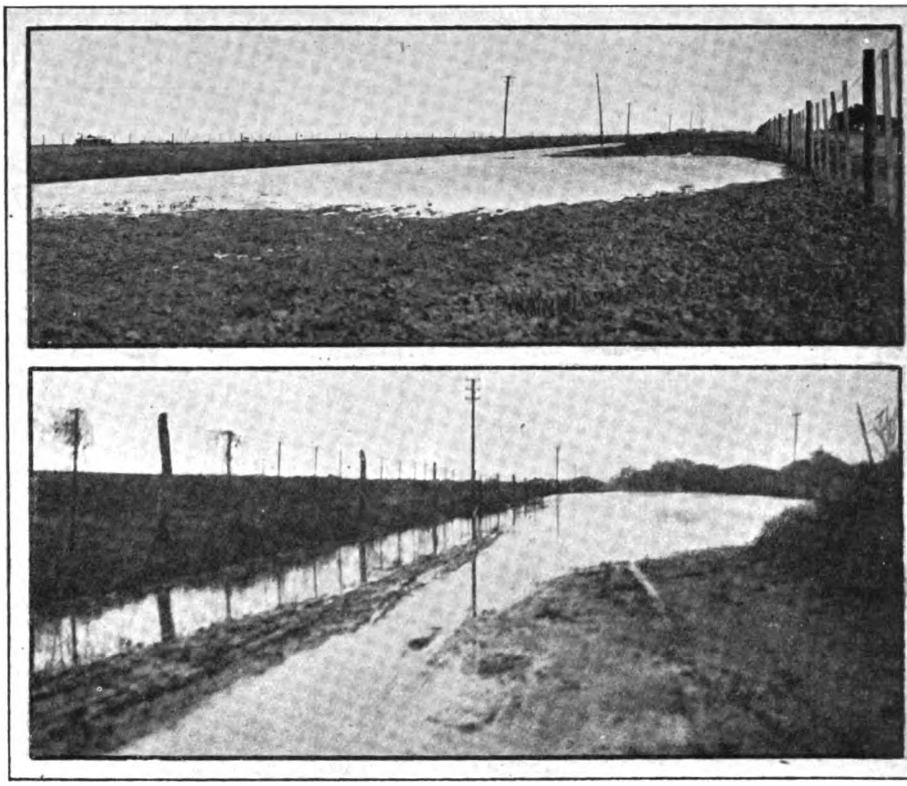
Latin-America is thinking to-day almost entirely of hard-surfacing its roads. This is so despite the high cost and physical difficulties, such, for instance, as in the Argentine where stone is obtained only after long rail or water shipment. In fact, one authority whose insight cannot be doubted declares that the first movement in any road campaign in South America is to overcome the desire for hard-surfaced highways. The graded earth road is much more suitable for a sparsely settled territory where land holdings are generally large and roads of this kind can be obtained in a fraction of the time that would be required to finance and build with macadam or concrete.

The duty of the automotive exporter is to further this propaganda and to aid in every manner possible in put-

ting it across. Passable roads, improved for traffic, must be cut through from town to town and existing roads must be graded and drained so that they will permit passage of cars and light trucks during the greater part of the year. No agency is so well prepared to assist in such campaigns as the automotive exporter and manufacturer. To them should fall a great deal of the preparatory work, just as it has here.

In recent weeks, communications on this subject have been received from Mexico, Peru, Chile, the Argentine and Brazil. Each of these countries is seeking light as to how it may pull itself out of the mud. Automobile and road associations have been formed or are in process of organization to further the work and each is sincerely desirous of getting better highways.

In Chile, the automobile club of Valparaiso is working upon the road between that city and Santiago, the capital, a stretch of some 150 kilometers that, once opened, will be dotted with motor cars speeding between the two chief centers. From Puerto Montt, far to the south in the same country, comes a similar word that improvements are under way. From Lima, Peru, the sentiment is expressed that road work is of prime necessity and elsewhere on the west and the east coast the same may be heard.



Improper drainage has made these Argentine roads almost impassable. To grade them above the water is a task requiring but little mechanical equipment and time

In São Paulo, Brazil, notable work already has been accomplished in getting highways built by co-operative effort. Uruguay has probably a better mileage of good roads than any other country in South America and, in Argentina, success has attended those efforts which have been made to grade up the earth roads and to maintain them either by governmental or co-operative effort of the estanciero owners. Frequent testimony is heard to the effect that many roads in the Argentine require grading or improvement in only a few stretches to make them suitable for many miles of travel.

In Latin-America, as in Australia and South Africa, there are many motor clubs and, in some cities, associations of automobile dealers. They are potent factors in getting road activities under way and, with them, the automotive exporters should work in close union. As an example of what such clubs may do, the Jalisco Automobile Club of Guadalajara, Mexico, might be cited. It has gotten behind several road projects. One of the latest such projects in the Guadalajara district is the road from that city to Colonia Seatle, which was formally opened on Dec. 1, 1920.

Latin-America is close at hand and from it may be gained the road lessons that should be applied in all those developing countries of the world. Conditions are the same in each and the reward for work accomplished will be similar.

This article cannot be completed without a word about China and its future road activities. The Celestial Kingdom, it cannot be doubted, is at the doorway of much building. Of that there is every testimony:

"Just at present, there is more interest being shown in good roads in China than has been manifested in centuries; yet they know little or nothing about it," says a recent letter from Shanghai. "A good roads movement would mean millions to the exporters and they should get behind it."

Coincident with this, is the announcement of the Bureau of Foreign and Domestic Commerce that a road making convention and exhibition of road constructing machinery will be held at Shanghai in May of this year under the auspices of the roads committee of the Pan Pacific Association. Two main roads, the bureau adds, are under contemplation for construction, one from Shanghai to Hangchow, the other Shanghai to Nanking.

THE use of radio communication, both telegraph and telephone, on the military airplane is, perhaps, the latest application of radio science, increasing tenfold the usefulness of the airplane and already influencing the design of military aircraft. The dots and dashes of the Morse code transmitted from the trailing aerial of the airplane carry to the ears of the artillery battery commander the correction for each shot fired, enabling him to group his hits on an invisible target with a degree of accuracy as great as is possible when the target can be seen, or bring to a waiting general news of enemy troop movement observed from the air.

Squadrons of attacking planes can be maneuvered in flight by means of the wireless telephone from the airplane of the squadron commander or from the ground as easily as a company of infantry is handled. By the same means machines engaged in aerial combat and outnumbered may call for assistance.

Bombing planes lost in the fog or darkness are directed unerringly to the home airdrome by the radio direction finder and airplanes without pilots, controlled entirely by radio, are already a reality.

The Air Service of the Army, realizing the importance of this newest phase of radio, has established a school for the training of personnel to install, operate and maintain the radio equipment of airplanes at all the flying fields throughout the country.

Unemployment a Vital Problem in Great Britain

Unemployment always constitutes an important phase of the British labor problem. Now it is acute, and must be definitely met if serious consequences are not to ensue. Mr. Tipper explains certain phases of the problem necessary to an understanding of Mr. Northcott's article, following.

By Harry Tipper

NOTHING could better illustrate the difference between the conditions which exist in Great Britain and those obtaining in this country than the approach to the question of employment. The subject is an old one and one of those which has been discussed from all sides a great many times. In this country it has not assumed important dimensions except for very brief periods, whereas in Great Britain unemployment has been a serious problem for many years.

The spectre of starvation has been very close to a considerable percentage of the people at all times in that country, and the fear which is caused by the constant battle with actual hunger is very much more firmly implanted in the rank and file of the workers. Some time before the war outdoor relief, almshouse population and pauperism had reached as high as 26 per cent in some years, and for many years the problem has been a severe one. No one familiar with the industrial conditions in Great Britain in the last twenty-five years could eliminate from his experience the knowledge of the economic conditions of a considerable proportion of the workers in some of the large cities.

One of my friends whose father was a miner in Scotland told me how the family was brought up by the ingenuity of the mother on a wage which never grew larger than $3 per week. It is a good many years since the volume of trade secured by Great Britain has been so continuously equal to the manufacturing capacity that the whole of the working population was permanently employed.

As a consequence, for twenty years at least, before the war, a percentage of the population was out of work at all times and the government relief, charitable work and so forth, were continuously employed in providing at least a measure of food and shelter to these people.

This condition explains a great deal in the following article, which would be without point otherwise. It will serve to illuminate the government unemployment insurance and the demand for greater security against unemployment on the part of labor. It will indicate also the reason for the "ca'canny" attitude of the labor unions in connection with production. It is significant that this Scottish term, originating in the poorest part of Great Britain, has become a part of the terminology wherever trade unions exist. Where a certain percentage of the workers, even the skilled workers, were unable to find permanent employment, it was obvious that they stretched out to the utmost whatever jobs they secured. No man who was constantly in fear of starvation for himself and his family would do otherwise.

This whole problem of unemployment indicates the growth of industrial difficulties in a country where the agricultural occupation has become entirely subsidiary and the manufacturing capacity has grown far beyond the capacity for absorption in the country itself.

This article is interesting from another standpoint. It indicates the considerations involved in a country where the workers are thoroughly organized and the attitude of those workers to the question of profits upon capital and the position of government in relation to industrial affairs.

The bitterness of the workers' struggle for a decent living and a larger amount of comfort in Great Britain has colored the whole development of the trade union and has affected the whole body of public opinion in regard to the national aspect of industrial problems.

This comment is necessary to an understanding of the significance of the following material prepared by our English correspondent, Clarence H. Northcott.

THERE came into my hands recently the house organ of the Dennison Manufacturing Company of Framingham, Mass., in the December issue of which were printed the articles governing the control and use of the Unemployment Fund set up by this firm. No information was available as to the formation and nature of the fund, but the paragraphs printed showed that the firm had in mind both the prevention and relief of unemployment. The committee in charge of the fund was commissioned to "study methods of preventing and relieving unemployment." The chief method cited for preventing unemployment was that of transferring an employee for whom there was no work to another part of the plant where there was work. It was stipulated, further, that the principle of "last to come, first to go" should apply to such transfers or to any "layoffs." The most interesting part of the scheme is the extent of unemployment compensation. While the condition of the fund permits, it is expected that compensation for employees without dependents shall reach 60 per cent of regular rates, and for employees with dependents 80 per cent. To ascertain regular rates, the averate earnings of the previous six weeks will be calculated. While no minimum sums are mentioned, the committee are empowered from time to time to establish such for men and women, with and without dependents respectively,

and to pay these sums whenever they exceed the regular percentage compensation. This compensation is payable for all unemployment in excess of one pay roll day, including holidays per pay week, and two pay roll days excluding holidays, in any four weeks, but will not cover any lay-offs of less than a half day at any time. The rates, however, are subject to reconsideration after payment has been made for six consecutive days.

A noteworthy and rather unique feature of the fund is the provision for compensation to employees transferred or those who have secured work outside the factory. In these cases it seems the desire of the firm that such men and women should receive up to 90 per cent of their regular wage rate with the company. The same provision applies to a man transferred to another department. If, however, such transfer is made, not to avoid unemployment but to retain the services of a valued employee, the compensation is to be debited to the operating expense of the company, not to the unemployment fund.

This pronouncement is of great interest to employers in Great Britain to-day. The wave of depression which passed over Japan and America has reached Europe. In Great Britain unemployment is fairly general, and has touched most trades. Great Britain is so largely an exporting nation that curtailment of buying in such markets as Asia, South America and Europe affects her seriously.

The automobile and engineering trades are feeling the depression acutely. The former was badly hit by the molders' strike at the end of 1919, which interfered greatly with production schedules. In consequence, makers missed last summer's markets. This reacted on the rubber firms.

At the same time cotton, wool and shoes felt the drop in wholesale prices, the restriction of credit by the banks and the thrift of the consumer who refused to buy at the inflated prices ruling. The slump became serious and the year 1920 closed in industrial gloom.

Unemployment has always been a gaunt demon in Great Britain, but this time he wears a savage as well as a hungry face. Men who fought for years in all quarters of the globe and were always well fed and well clothed while they offered their lives to save their country are not going to accept cold, hunger and starvation tamely. The British worker is no Bolshevist, but he is a stubborn fighter for right, and he has accepted the doctrine that industry owes him maintenance in times of unemployment. He has invested his life and well-being in the industry and holds that his ill-requited labor for it in times of its prosperity shall be balanced by a sustenance wage in bad times. If he cannot get this, which he has come to consider his rights, he seems determined to set up a new form of industry. What it may be, whether syndicalism or guild socialism, he is not clear, but he has convinced the employers of Great Britain that he must receive some decent maintenance during unemployment. Their difficulty is twofold.

First, in very few cases have they worked out a program to meet such an emergency. In the second place, they have not allocated any reserves for this purpose when reserves were abundant, and they are afraid that they cannot find any now for the purpose. As one of them put it, the position they are in is like that of a man seeking an insurance upon his house while one corner of it is alight.

The government scheme is of little value. It provides that, in return for certain weekly contributions by employers and workers alike, supplemented by the State, and on fulfillment of certain statutory conditions, men unemployed may receive benefit to the extent of 15s. a week and women 12s. a week. This payment is a mere dole. It is not sufficient to provide food for one individual, without taking account of dependents or of such other necessities as rent and clothing. It is true that most trade unions pay unemployment benefit in return for a small payment from their members. This benefit ranges from 1s. to over 2s. per day, but, as the unions have not large reserves, it cannot be continued for a very long period. The cotton trade unions, who have been paying out since the end of September, have already almost reached the bottom of their treasury. The government benefit, plus that of the unions, is only a small fraction of the normal wage earned. In the industry with which the writer is connected, the minimum time wage for an adult man is 72s. 6d. If unemployed, such a worker would receive only 21s. from state and trade union, that is, about 30 per cent of his regular rate.

An endeavor to find a better scheme that would apply to every industry has been made recently by a group of employers and representatives of labor, who have published their scheme anonymously. The writer, who is acquainted with the employers concerned, can guarantee that they represent big, progressive businesses and bear names known on both sides of the Atlantic. In their discussions they have been assisted by financiers, economists and statisticians, and have consulted freely with all schools of labor.

The opening paragraph of their scheme is one which bears quotation, as showing the economic motive behind such a piece of constructive work:

"The suffering caused by unemployment has been generally recognized, but too little attention has been paid to its reactions on production. Industry moves in a vicious circle. Additional production is necessary if poverty is to be abolished and unemployment relieved. Yet uninformed labor instinctively resists every kind of productive improvement lest it should cause unemployment. Improvements in machinery, in the reorganization of labor with a view to using more effectively skilled grades by means of dilution and in other ways, the introduction of systems of payment by results which have been proved to stimulate production, are all resisted more or less openly, and in every case fear of unemployment is largely responsible for the resistance. It is true that the fear may be largely unjustified, and that 'ca'canny' may accentuate the very evil it is intended to prevent. But such facts are irrelevant. The rank and file of labor believe that improvements bring unemployment and no one has ever succeeded in convincing them that they are wrong. Nor is it any use to argue and make agreements with the leaders of labor; it is the instinctive action of the rank and file that counts. An immense potential increase in the productivity of industry awaits release, and only the complete removal of the menace of unemployment can release it."

As this quotation shows, these employers believe that the future efficiency of British industry depends on giving reasonable security to the worker. They are not satisfied with the government scheme, since the benefits are not sufficient to keep a household together, hence cannot remove "the fear of unemployment or the industrial policy to which this fear gives rise among the workers." Yet, relying on the British preference for governmental action in such matters of social relief, they demand that the State should undertake to deal with this problem on effective and permanent lines, admitting the claim of all adult wage-earners, who are willing and

capable of work, to either suitable employment or adequate maintenance throughout their working lives.

Their proposals are for the creation of a fund which would be sufficient to pay certain benefits. A single person should receive in unemployment compensation 50 per cent of average earnings, with 10 per cent additional for a dependent wife, and 5 per cent for each of not more than three dependent children under 16 years, with a maximum of £5 a week.

Benefits would be payable after three days' unemployment, and should aggregate not more than one week for every six weekly contributions made by the worker, but might extend to 26 weeks. The workers' contribution to this fund is placed at one penny in every 10s. of his wage, that is, a little less than 1 per cent per week. The State is to contribute £4,000,000 and pay the cost of administration, and what more is needed to pay the benefits above sketched, it is suggested, shall be raised by a levy on employers. Their total is estimated on present wage rates at £37,000,000. The promoters calculate that if such a scheme resulted in a 10 per cent increase in production, this would equal 100 millions, or nearly twice the total estimated cost of the scheme. By reason of the psychology of the British worker, such an increase is by no means fantastical. It should be added that the scheme is equally applicable to short time, that is, to work less than the normal working week.

This suggested scheme has been followed promptly by a concrete modification of it in the case of Messrs. Rowntree & Co., cocoa and chocolate manufacturers, who have been pioneers in much social and ameliorative work. Their project went into operation on Jan. 1, 1921, and was drafted in the light of the firm's position, financial and industrial. It applies to all of their workers between the ages of 20 and pension age (65 years) who have been discharged solely through depression of trade, and who, immediately prior to their discharge, had been in the employ of the company continuously for six months. Benefit will take account of length of service, being at the rate of one week for each two months of service up to 2½ years, and one week for each complete year beyond that period. That is, an employee who had been with the company 2½ years would receive benefit from them for the same period as the State grants it.

It is expected by the company that benefits shall total the percentages suggested in the employers' scheme set forth in preceding paragraphs. In addition to the percentages and maximum there set forth, Rowntree & Co. stipulate for a maximum payment of 25s. a week. In these percentage totals are counted the benefits paid by the State and the trade unions. As the largest trade union in their works, which covers in its membership 95 per cent of the unskilled men eligible and 50 per cent of the women, pays 6s. a week, this sum is added to the 15s. paid by the State, and the firm undertakes to pay the residuary cost. Thus, if a single man, without dependents, earning on an average 80s. a week, is discharged through shortage of work, he receives, unless otherwise disqualified, 15s. from the State, 6s. from the trade union and 19s. from Rowntree & Co., bringing his total benefit up to 40s., or 50 per cent of his wage. If the unemployed man is a pieceworker, earning on an average 92s. a week, and has a wife and three dependent children, then in addition to the State and trade union benefits as above, he receives 48s. from Rowntree & Co., making 69s., or 75 per cent of his average earnings, which are calculated on the basis of the preceding quarter.

To meet these obligations, the firm has set aside an initial reserve of £10,000, to which it will add each year from 1921 onward a sum equal to 1 per cent of its wage bill, until the fund reaches £50,000, or 5 per cent of the wage bill, whichever is the greater. Thereafter it will set aside annually such sums, not exceeding 1 per cent of the wage bill, as will keep the fund up to the maximum aimed at.

It is proposed to apply the provisions of this scheme to partial unemployment or short time, but not until 10 per cent of normal full time has been lost by a time worker and 15 per cent by a pieceworker. Time so lost in excess of 10 per cent or 15 per cent respectively will be paid for at a rate proportionate to full unemployment benefit.

It should be added that this scheme was drawn up by the directors of the company and their social and economic advisers, with active assistance from five delegates from the Central Works Council, whose co-operation was requested. The names of those who are about to be dismissed owing to shortage of work are submitted to the shop stewards of each department. In general, men who are bad time keepers or are inefficient are those selected for dismissal, while others are put onto short time. This action is the choice of the workers, who are consequently interested in the right selection of the "slackers." It is true there have been cases where shop stewards have challenged the manager's selection of inefficients, but, on the other hand, when a disgruntled dismissed man voiced his complaint in the local press, two leading shop stewards stoutly defended the firm's action. The fund is to be administered by a committee of nine appointed by the Central Works Council.

To sum up, the two instances of unemployment relief, that of the Dennison Manufacturing Co. and of Rowntree & Co., point the way to a greater humanizing of industry. They take account of the fears and aspirations of the workers, and by removing the incentive to "ca'cannying," offer the prospect of restoring efficiency, interest and initiative.

They remove the burden from the individual and put it onto the Atlantean shoulders of industry. They show an appreciation of the fact that capital, while enjoying the profits, must take the risks of industry. They are an attempt to regularize industry and rob its cyclical movement of boom and panic of much of its terror to the workers, to whom security will furnish a motive for more intelligent and friendly interest in the productive process.

C. H. NORTHCOTT.

AT a recent meeting of the Royal Aeronautical Society of Great Britain, Lord Mountagu of Beaulieu attempted to make a comparison of the cost of transport by air and by other standard methods. He put the cost of road-motor-transport at from 14 to 20 cents per ton-mile (1d = 2c), of motor-bus and charabancs at about 40 cents per ton or 2.5 cents per passenger mile, of railways at 5 cents per ton-mile. The cost of shipping per ton-mile is so low and the ton mileage is so difficult to discover that shipping is treated on the basis of gross tonnage of ship and cargo combined, and varies between 0.076 and 0.144 cents per ton-mile. The cost of passenger traffic per ship-mile varies between 2.22 and 3.6 cents.

For the airplane the author estimates that 88 cents per ton-mile would afford a reasonable profit, and that therefore the airplane can only compete with existing facilities where speed is of great value. The cost of R.34's trip to America is stated to have been $5.64 per ship-mile. The English-to-India trip with a similar ship is $9.94 per mile, including interest on capital and cost of running both ship and the necessary bases. With 15 tons available for useful load, this gives 71 cents per ton-mile.

What Is Normal?

THERE is much discussion to-day of a return to "normal." Just what this means is difficult to say. Does it mean to a standard of business in 1914, 1917 or some other year? Why not take the peak of the first half of 1920 as normal and seek to bring business to that standard? Why should the American business man of to-day walk backwards?

The writer has heard the subject of "getting back to normal" discussed many times recently and invariably some practical man in the group has asked the question that is so obvious. Only a few days ago a sales manager told of declining to answer a questionnaire that was based on "normal" because he did not know what the compiler of the questionnaire had in mind.

The Chamber of Commerce of the United States has just sent to its members a letter of inquiry seeking information as to how business men are "cutting down their operating expenses." In the questions themselves everything is based on the idea that "normal" is less than was the standard of business a few months ago.

One of these questions is especially interesting. It reads:

"What have you done to reduce your publicity costs to a normal basis?"

Frankly we do not believe there is a business man in this country who can answer that question with an assurance that he is right. Several points of doubt arise on first reading. Here are a few:

What is legitimate publicity?

What is a normal cost of publicity?

Is publicity selling the product, or spending money?

If publicity is sales promotion, should it not increase when business is dull?

It would appear to us that it is quite necessary for the Chamber to effect several definitions before considering the replies to this question.

A National Tractor Show

By David Beecroft

THERE is one best place to hold the national tractor show and that is Chicago.

There is one best time to hold it and that is the week of the Chicago Motor Car Show, or the week following it. The week of the motor car show would be best if ample hotel accommodations can be had in Chicago hotels.

We have seen national tractor shows in Kansas City and Columbus, which have been truly national so far as exhibits and display of tractors and farm power equipment and parts are concerned, but we must stop here.

These shows were not national from the attendance point of view.

The Columbus show this year was anything but national in attendance. The dealers were largely from Ohio and adjacent states. True there were some from distant points but in numbers so small as to be insignificant.

It is impossible to hold a national tractor show dependent upon a farmer attendance. The country is too large for that. Upwards of 75 per cent of the Columbus show attendance was farmers and of these 95 per cent were from Ohio. The Columbus show was just a local show from the attendance viewpoint.

No attempt should be made to stage a national consumer tractor show.

The national tractor show must be for distributors and dealers. Chicago is the logical and geographical center for such a show. To get the distributors the week of the Chicago motor car show is best. That week is best not only for distributors but for parts and accessory manufacturers.

At the recent Columbus show our analysis of exhibitors shows 52 tractor makers, 78 makers of parts or accessories for tractors, and 49 makers of farm equipment to 80 tractors for farm use.

A majority of the parts makers have participated in tractor shows for several years, due to the industry being in the formative state. These same makers supported the national motor car shows in New York City and Chicago in the formative days of the motor car, but many years ago withdrew. To-day they maintain headquarters in hotels in New York City or

Chicago during show weeks and accomplish their end. It is expected that history will repeat itself and they will soon withdraw from tractor shows as active exhibitors. There is little for any of them in consumer or dealer attendance. It is true they add to the magnitude of the exposition, but not so much as many think to the real motif of the exposition.

Were the tractor show held in Chicago during motor car show week, these parts makers could meet the tractor industry just as to-day they meet the car and truck industry. Their expenses would be proportionately reduced and the tractor show would not be robbed of much, if any, of its tangible value.

The Columbus tractor show display housed in seven buildings was a most impressive one. Each tractor exhibitor had ample display space, but it would have been a better show if many parts makers had not been present and their space given to tractor and equipment makers and the exhibitors housed in three instead of seven buildings. The show was too scattered.

The tractor manufacturers are looking for dealers and distributors, and will continue to look for them. The imperative problem of better tractor service will result in a heavy annual change in dealers for some years to come. Many distributors voiced this sentiment at the Columbus show. To meet this situation the national tractor show must for years be a dealer and distributor show. It must be a national show located in a center that has national significance, a national appeal to the 48 states, because the tractor, whether used on a farm or in industry, is and will each year become more truly national in use, in distribution, and consequently in service. Chicago has a national appeal as strong as if not stronger than New York City.

Chicago has exhibit spaces suitable in either the Dexter Park Pavilion in the Union Stock Yards, where the National Live Stock Exposition is held annually, or in the new Municipal Pier on the lake front. The very name of Chicago gives an international appeal, and as we must have export trade and sell to the 100 nations of the world, so we must have our national exposition located in centers of international appeal and character—Chicago will draw immeasurably better than Kansas City, Columbus, Minneapolis, St. Louis, Cincinnati, Cleveland, Detroit, or other smaller cities.

The show should be staged directly by the National Implement and Vehicle Association and not by any local tractor club, just as a score of other national industrial shows are staged by the manufacturers constituting these industries and not by the distributors and brokers merchandising the products. Such a show will not interfere with regional tractor shows.

On Trial

PERSONNEL management is on trial. During times of labor shortage and good profits it flourished in nearly every industrial plant. Huge sums were expended on personnel departments of one kind and another. Strong claims were made in its behalf as a vital factor in production and in modern industrial organization. In many cases these claims were fulfilled; in many others they were not.

The personnel department has before it to-day just as difficult and pressing problems as it had a year ago. The difficulty of the labor situation has temporarily abated, but wrong methods at this time on the part of manufacturers will merely cause them to reap a future whirlwind. The need for effective, intelligent personnel work is great at the present time.

Together with this great need for effective personnel work is present the need for the elimination from all factory organizations of every non-essential activity. Insofar as personnel management recognizes the fundamental natures of the problems presented in regard to human relationships and insofar as it formulates constructive plans for meeting those problems, just so far will it justify its existence and fulfill its very necessary function.

Meyer Bloomfield said recently, "The war gave personnel management a somewhat regrettable impetus; the present depression has helped to weed out many undesirable features, although some good things have gone with them."

Sacrificing Economy for Performance

THE comparison of passenger cars on a basis of displacement per ton-foot which appears on another page of this issue should give food for thought to those responsible for the design of these and other cars, as well as to other engineers who are interested in factors which govern performance and fuel consumption. It is interesting to note that some cars use nearly double the displacement per ton-foot which others employ. The conclusion to be drawn from this comparison is that economy in fuel consumption is regarded by many users as altogether secondary to other performance considerations for it is evident that, other things being equal, the car which has a high displacement per ton-foot will run with a lower percentage of full load than the car with low displacement, and consequently use more fuel per b. hp. than otherwise. Of course, other factors, such as compression ratios and internal friction vary considerably, but it is evident that much is being sacrificed in some cases to get performance—good hill climbing ability and a high rate of acceleration—at the expense of increased fuel consumption.

The foregoing takes account only of operation on high gear. By a proper selection of transmission gears it is possible to vary consumption per ton mile, owing to the better load factor that can be secured, but this may involve more gear changing than the average operator likes. Every engineer has, of course, to make selections which involve compromises depending upon the various factors involved, but it seems unfortunate that so much is sacrificed in fuel economy when there is a real need of better utilization of national fuel resources. It is significant that among the cars showing the lowest displacement per ton-foot are some whose hill climbing and accelerating ability leaves little to be desired.

Steel Prices Main Factor, Ford Says

Prohibitive Costs Alone Can Prevent Full Speed Ahead

Frank Statement of Plans and Prices Are Given in Exclusive Interview

By Roger H. Burlingame

DETROIT, Feb. 25.—Production in the great Ford factory at Highland Park will be fully 75 per cent of capacity by the end of March unless it is made impossible by prohibitive steel prices.

This outstanding fact was disclosed by Henry Ford to-day in an exclusive interview with a representative of the Class Journal publications. The announcement was included in the first detailed statement he has yet made for publication of his factory plans and policies.

Seated by a window in his office with a half dozen Ford executives grouped about the room, Mr. Ford answered questions put to him without reservation, entering into discussion with the interviewer at times as to the advisability of publication, subordinating his opinion in instances to that of his executives and the newspaper man, and throughout the interview, lasting about an hour, never once sought to take the lead or divert the trend of questions.

With his chair tilted back, legs crossed, and his hands clasped behind his head, following a cordial greeting, the most talked of man in the industrial world today adjusted himself in a position of comfort and with patient forbearance and a smile playing about his face continually, listened and replied promptly to questions of minor detail with as much interest as though in conference on world problems.

It was suggested at the outset that the interview was for publication in magazines devoted solely to the upbuilding of the automotive industry rather than for public consumption, and Mr. Ford readily acquiesced in the request that questions vitally affecting the industry might be put to him.

Looks to Normal Output

It was during his reply to a question as to plans for factory operations looking to return to normal production that Mr. Ford sounded the big note when he declared that operations in April and May and for the future were contingent on the price of steel, adding:

"If we have to close again it will be due to the attitude of steel manufacturers."

And right here the man who talks in hundreds of millions showed his grasp of the details of his organization when, in emphasizing his point that steel is the big factor, he approximated the weight of the top, tires, glass and floor-boards for comparison.

The issue was brought up when Edsel Ford suggested that not only steel prices but prices of all materials would have an effect, his father stressing the point that steel was all important and prohibitive prices the real handicap to uninterrupted production.

Frequently throughout the interview Mr. Ford made reference to financiers, referring to them as "money sharks," and there was a note of exultation in his voice when, in answer to the question as to whether he cared to discuss the many reports of financial stress and alleged efforts to float a loan, he said:

Not Building Without Money

"The best answer to that question is employment and production figures just given you and the fact that we are going to build 80,000 cars in March. We must pay for materials and labor and that means a considerable sum."

The many rumors regarding conditions at Highland Park and the reports giving the number of men employed in totals ranging from 5000 to 20,000, were set at rest when Mr. Ford declared that since the reopening of the plant Jan. 31 with approximately 10,000 men, the force had been increased steadily until to-day's total of 15,800 was reached. The force will be increased in conformity with sales and demand, he said, until normal operations again are resumed.

Won't Need as Many Men

It was made plain, however, that the force never would reach the total employed during the peak last year for it has been demonstrated beyond question that the maximum of production requirements can be reached with a materially decreased force due to greater efficiency and more conscientious effort. In this connection Mr. Ford said:

"It is the universal policy and the logical course to minimize operation and production costs and evidence multiplies that by stimulating men to greater effort

(*Continued on page* 531)

HIGHLAND PARK PLANT WILL BE RUNNING 75 PER CENT CAPACITY BY MARCH 31

DETROIT, Feb. 25—These facts about his gigantic business enterprises were disclosed by Henry Ford to-day in an exclusive interview with a representative of the Class Journal publications:

That 15,800 employees were working in the Highland Park plant to-day.

That 2860 cars were produced in Highland Park and branches yesterday.

That 2505 engines were built at Highland Park Wednesday.

That there were 95,000 cars in the hands of dealers and 30,000 in process of construction at the branches when the Highland Park plant closed Dec. 24.

That 57,000 cars were sold during January, liquidating the 30,000 completed in the branches and 27,000 of the dealer stocks.

That retail sales for the first half of February were 42,000.

That total production for February will be 35,000.

That sales, if the ratio continues through February, will approximate 85,000, assuring liquidation of 50,000 more of the dealer stock.

That dealer requirements for March are 70,000, necessitating a production schedule of 3100 daily, within 1100 of the record for daily production.

That working forces and production will be increased steadily until normal production is reached.

That continued operation and increasing production is contingent on steel prices and that if the company is forced to again shut down it will be due solely to prohibitive steel prices.

That there will be no reduction in the wages on specific jobs and no reduction in the minimum scale.

That the Ford Motor Co.'s reply to reports of financial stress is the announcement of steadily increasing working forces and output scheduled to reach close to normal by the end of March.

That the executives now in charge at Highland Park and River Rouge will constitute the permanent official personnel with official titles in most cases eliminated and concerted efforts being directed to development of Ford products and policies.

That 2700 men were employed at River Rouge to-day, 1700 having been added to the 1000 which have been working there without interruption throughout the period of depression.

That a production schedule of 100 tractors daily was started at the Rouge plant to-day, which will be increased as demand requires.

Industry Shows Continued Gains

Chrysler Cheerful on Business Outlook

Declares Willys Plants Ready to Meet Competition—Last of Year Best

TOLEDO, Feb. 28—Walter P. Chrysler, executive vice-president of the Willys-Overland Co., and all the Willys interests, and Charles B. Wilson, vice-president in charge of the plant here, have been in conference this week looking after production plans.

The company has less than 1700 cars in process of manufacture at the present time, indicating that sales have been progressing fairly well since the automobile shows last month. The plan has been to manufacture only on demand of dealers. No definite date has been set for the beginning of a production plan, but it is understood that possibly a small schedule may be put into effect about March 15.

"It's a great deal more difficult to build up a force than to tear one down," said Chrysler. "That's the task we have on hand now and we are going to go forward and build the organization over from top to bottom. There will be all sorts of changes in the next few weeks. Many new men will be coming in and some will be going.

"We have had to eliminate extravagance in the administration of this plant, and we have made some deep cuts. There is competition ahead in the motor car industry."

Chrysler said he had avoided making any forecasts on the industrial conditions of the future because he couldn't make good guesses on affairs so contingent upon many world-wide economic factors.

"We have been through crises in manufacturing before—not quite so bad as this one we have experienced recently—but involving largely the same principles, and we are quite optimistic right now," he declared.

Would Establish Money Value

"The experts have been bringing out figures for us and we have been trying to find out what our dollar will purchase. Some say it will buy about 80 cents worth of what it could have bought before the war. But we don't know. Things are becoming more stabilized every day—we can see that.

"We have a feeling that the last three-quarters of the year will show a pick-up of about 40 per cent in business generally. But that's only a guess." Chrysler would make no comment on the financial arrangements planned for the Willys organizations.

MOSTLY SUNSHINE SEEN FOR TRADE IN MARCH

A weather forecast for the automotive industry for March indicates that while it will be partly cloudy there will be more of sunshine than there has been for several months, and that as spring approaches the "fair and warmer" flag will be displayed with increasing frequency. Here are some of the signs that the clouds are breaking:

Ford is preparing for production on a basis of 75 per cent of capacity by the last of this month.

Production in the various General Motors plants has reached 50 per cent of normal.

Most Detroit manufacturers are adding to their forces and speeding up production to meet increased orders.

Sentiment in the Detroit territory is much more hopeful than it has been for weeks.

Akron tire factories show more signs of life than they have since last spring.

Automotive plants in various parts of the country are resuming production on a small scale and gradually augmenting their forces.

Dealers in most of the industrial districts report steadily mounting sales, and even in farming sections there is increased interest in motor vehicles.

The upward trend includes both passenger cars and trucks.

Peugeot Not to Build Cars in United States

PARIS, Feb. 19—(*Special Correspondence*)—There is no intention of the French Peugeot Co. to build an automobile factory in America. Negotiations have been in hand for several months with American promoters who wish to purchase or construct a factory in the United States where Peugeot automobiles will be built under license. The French company has agreed to sell their license to this group and to supply the necessary technical staff providing American financial backing is secured. According to a statement made by one of the officials of the Peugeot company to an AUTOMOTIVE INDUSTRIES representative, American financial assistance has not yet been secured, and until this is obtained nothing will be done in the matter.

Tire Business Takes Quick Upward Turn

Experiences Greatest Uplift Since Depression Began—Prepare for Ford Orders

AKRON, Feb. 28—The rubber industry in Akron has shown more life during the past ten days, than at any time since the inception of the current business depression. Two recent events of outstanding importance indicate a strong upward trend which augurs well for an early return to conditions in the industry nearly approaching normal.

First of these was announcement by the B. F. Goodrich Co., that 30,000 small size tires had been shipped to the Ford plant in Detroit. This is the largest single shipment of tires made in Akron in eight months.

Second was announcement by Goodyear Tire & Rubber Co. officials of nearly a 100 per cent increase in production, effective the last week of February. The Goodyear increase does not let down the bars for more men just at present, but for those now employed by the company it means longer hours. The increased production ticket calls for 60,000 tires a week and necessitates adding another work day.

Notice that the Ford plants would soon be running full force also has stimulated tire production, and half a dozen Akron companies holding Ford orders, are increasing production so as to be prepared for early shipment.

The Oldfield Tire Co., latest comer to Akron, and of which Barney Oldfield, erstwhile motor speedway champion is president, is laying plans for substantial increases in production this year. The Goodrich Co., while having an ample surplus on hand to accommodate immediate shipments, is contemplating an increase in production in the near future. Miller Rubber is opening up its mechanical goods and rubber sole and heel departments, and Firestone is also showing more signs of life. The Portage Rubber Co. reports as much business booked so far this year, as during all of last year, and expects to increase its volume in 1921 by more than 100 per cent.

CLEVELAND BUSINESS BETTER

CLEVELAND, Feb. 28—The upward trend of business which began with the automobile show continues, although the increase is gradual. There has been decided improvement in sentiment, however, and automotive manufacturers are much encouraged by the outlook. One plant making automobile bodies reports the addition of 350 men to its payroll.

February Deliveries Approximate 1920

Actual Turnover of Business Compares with Year Previous —General Outlook Better

NEW YORK, Feb. 28—So far as cars actually sold and delivered are concerned, this month has developed a normal February sales volume. The demand for cars does not begin to compare with the pressure of a year ago, but the results in actual sales are about equal, because last year the dealers couldn't get the cars they needed on account of the traffic conditions, and this year the reduced factory schedules are barely meeting the demand.

With a few exceptions, and these principally among the higher price cars, the New York retail market has developed a gradually increasing volume of business that is regarded as entirely satisfactory.

One large distributer in the medium price cars, whose product is in the country's ten best sellers and whose contract calls for 6 per cent of the factory output, has found no difficulty in disposing of more than 10 per cent of his factory's output in the past month. This distributer's actual delivery of cars to owners follows a schedule approximately the same as in February last year. At least three other distributers of medium price cars in the New York territory are running ahead of actual deliveries during this period last year.

In the higher price cars there has been a lull of several days, following the tapering off of a fairly good market that developed just previous to the New York show early in January and reached its peak the latter part of January. But even with this condition existing to-day, there is considerable faith in the development of a stronger market as soon as the weather becomes settled. It is pointed out that February usually is a low sales month in this class.

The wholesale passenger car market is becoming somewhat steadier and is showing a healthful, sturdy increase, but a slow one. After experiencing a decidedly improved sales volume early in the month, the used car market is showing signs of sagging again.

The truck market, both wholesale and retail, is still showing the spotty tendencies that have characterized it for several weeks. While there is some general improvement, it has been slight.

SPRINGFIELD PLANTS BUSY

SPRINGFIELD, OHIO, Feb. 28—In a survey just made of industrial conditions in Springfield it was ascertained that the Springfield works of the International Harvester Co., now turning out motor trucks instead of agricultural implements, is operating a force above normal. It is now turning out 30 trucks a day.

The Westcott Motor Car Co. is employing 225 of its normal force of 250 men.

The Kelly-Springfield Motor Truck Co. is pushing ahead with production. Good sized orders are expected soon, it is announced. Reports from dealers show that conditions are encouraging.

The Victor Rubber Co. is turning out 300 cord tires daily. More than 200 out of the regular force of 350 men are now at work in the plant.

Durant Studies West for Assembly Location

SEATTLE, Feb. 26—C. M. Steeves, personal representative of W. C. Durant, formerly president of the General Motors Corp., is completing an exhaustive investigation of manufacturing possibilities on the Pacific Coast and is about to leave for the east to make his report. In automobile circles it is known that Durant and his associates plan the manufacturing on a big scale of an automobile which will sell for less than $1,000 and one of the several manufacturing plants to be built will be located on the Pacific Coast.

Steeves has made a survey of conditions in Los Angeles, San Francisco, Portland and Seattle. Civic organizations here were particularly active in seeing that Steeves did not overlook any of the advantages the city claims for an automobile manufacturing plant.

Steeves would give no intimation as to what his recommendations would be for the location of the proposed Pacific Coast plant.

Body and Glass Plants Increase Operations

TOLEDO, Feb. 28—The Milburn Wagon Co. is now employing 300 men on automobile bodies and Milburn electrics in the plant here, President Frank Suydam declared this week. He said business was increasing and that he expected to be taking on more men each week. The company is working on orders for bodies for the General Motors Corporation.

The Ford Plate Glass Co., which manufactures large quantities of glass for windshields and sedan bodies, opened a portion of its plant at Rossford near here with 600 men today.

HOMAN JOINS C. G. COMPANY

KALAMAZOO, MICH., Feb. 28—The name of the U. S. Auto Bumper Co., Chicago, has been changed to the C. G. Spring Bumper Co. Charles C. Homan, who for many years was purchasing agent at Willys-Overland and later vice-president of Hal Motor, Cleveland, which position he resigned to accept a commission in the Army in France, and who, since his return from abroad, has been connected with the Goodyear Tire & Rubber Co., has accepted the position as manager of the C. G. Spring Bumper Co. with headquarters at the office in Chicago. The company is controlled by Christian Girl.

Mining Communities Work at Full Speed

A. F. of L. Survey Shows Only Scattered Units Aside from Mines Near Normal

NEW YORK, Feb. 27—A survey of industrial and unemployment conditions being conducted by the American Federation of Labor shows conditions to be nearly normal in a few isolated districts despite the almost universal depression.

The places in which business is nearly normal are for the most part mining communities in which production activities seem to be progressing at full speed. The towns which are active because of mining work are Westville, Ill., Carlinville, Ill., Pittston, Pa., and Mahanoy City, Pa. The report from Pittston states that "Coal mines are on full time. The silk business has been dull but is taking on new life."

Four other small communities show normal activity for other reasons. In Oneida, N. Y., there have been several hundred men laid off from the factories but they were out of town men and have gone back to the farms where most of them came from. In Wisconsin Rapids, Wis., a paper mill town, few men are unemployed at the present time. Cloquet, Minn., another town in which a paper company forms the chief industry, reports that the paper company is doing a large amount of repair work on their dam and is also building another dam in the city, so that there is at least temporary employment for everyone.

These small scattered units, however, represent the only really encouraging reports thus far included in the survey. Industrial depression and unemployment is serious in nearly every other unit reported.

TO SELL REYNOLDS ASSETS

MT. CLEMENS, MICH., Feb. 28—Circuit Judge Tucker has signed an order directing Charles J. Reimold, receiver of the Reynolds Motor Truck Co., to sell at the factory in this city on March 14, all the assets of the company. These assets will be disposed of at auction in one parcel. No action has yet been taken by the stockholders who feel that their interests might be better protected if the company were thrown into bankruptcy, and if steps in this direction are not taken at once, the affairs of the corporation will be wound up as speedily as possible.

AMERICAN TIRE PLANT STARTS

YOUNGSTOWN, Feb. 28—Production of tires, tubes and hose was begun this week by the American Tire Corp., Niles, Ohio. This is the first actual operation since the company was incorporated two years ago. The output is expected to be 800 to 1000 tires per day. The company occupies the plant of the Engle Aircraft Co., which dissolved at the close of the war.

Anti-Dumping Bill Held Over in Senate

Manufacturers Support Suggested to Insure Early Action—Would Equalize Prices

WASHINGTON, Feb. 28—Senator Smoot of Utah, one of the most influential members of the Senate, advised AUTOMOTIVE INDUSTRIES to-day that the anti-dumping bill would undoubtedly protect American truck manufacturers and dealers from dumping of surplus army trucks here. The bill is pending on the Senate calendar and has passed the House. It provides for the assessment of special duties as a means to eliminate unfair competition and would operate, he said, to equalize the sales price.

This measure was introduced in the Senate Dec. 10, 1919, at a time when foreign competition became a real menace to American manufacturers. The bill was designed to provide revenue and encourage domestic industries through imposing duties. The Senate Committee on Finance directed Senator Smoot to report the bill April 8, 1920. Through parliamentary tactics, it was not considered in the second or the present session of the Sixty-sixth Congress.

The bill provides that whenever the purchase price of imported merchandise, dutiable or free, of a kind or class produced in this country, shall be less than the market value thereof, a special duty shall be assessed in the amount of the difference between the purchase price and the market value. This proviso, it would appear, would effectively squelch all efforts of English and French merchants to undersell the American dealers in trucks. Senator Smoot stated that this duty was a dumping duty and could be applied on the trucks despite the fact that the present tariff laws allow free entry as "goods returning to point of manufacture."

The act specifies that if there is no such actual market value, but the purchase price of the merchandise is less than American export prices for the same material, the tax shall be assessed on imports. The same applies to imports which are offered for sale in this country at prices less than cost of production for same equipment here.

Provides Penalty For Rebates

Another section of the House bill, as amended by the Senate Committee on Finance, provides a penalty for rebates and concessions which directly or indirectly effect a reduction or diminution of the purchase price or the selling price of the imported merchandise. It is believed that American truck manufacturers and dealers who have felt the effects of foreign competition in having American goods, originally sold to the Army, resold to foreigners and then offered on American markets at less than production cost, will support this measure and urge its immediate consideration at the extraordinary session of the Sixty-seventh Congress.

Senator Thomas, Democrat, of Colorado, who filed a minority report against the bill at the time it was reported out of committee, told AUTOMOTIVE INDUSTRIES that he believed that the bill could be strengthened, if necessary, to cover reimportations under conditions which confront American producers. He appeared interested in the report of the British and French invading domestic markets with rebuilt machines which escaped duty owing to original manufacture here. Senator Thomas would unquestionably press this matter, but his term expires at noon Friday, when the present Congress adjourns.

Palmerton to Manage Foreign Trade Bureau

NEW YORK, March 1—P. L. Palmerton, formerly in the foreign department of the Goodyear Tire & Rubber Co., has been appointed manager of the newly created foreign trade bureau of the Rubber Association of America. He is now organizing the work and expects in the near future to be able to supply members with information on the best means of carrying on trade with foreign countries as well as the best potential markets.

The executive committee of the Rubber Association is giving careful consideration to the subject of the support to be given various good-roads organizations, and it is hoped some program can be worked out upon which the entire automotive industry can unite. Another phase of this work is connected with the efforts of the Motor Vehicle Conference Committee to have enacted uniform state legislation in relation to load schedules, tire carrying capacities, etc.

The Rubber Association also has taken up the question of standardization in the sizes of automobile tires, and its research in this direction has emphasized the need for a technical committee which is to have as its primary purpose the consideration of tire standardization. A committee of five members of the executive committee has been appointed to comprise a technical committee which will consider all standardization projects of the industry.

TO ADJUST MAXWELL CLAIMS

INDIANAPOLIS, March 1—Charles Martindale of Indianapolis has been appointed by Judge Anderson in Federal Court here as master in chancery for the Maxwell Motor Co., Inc., to receive and adjust all claims of creditors against the company within the jurisdiction of Indiana. The action is preliminary to a reorganization of the Maxwell and Chalmers companies, which have been merged.

Appointment of the master was agreed to by the Maxwell company, according to attorneys who filed the petition. A master has been appointed in a similar way in Detroit and action in the District Court at Dayton, Ohio, is also contemplated, the attorneys said.

Oppose Insurance for Confiscation

Companies Find Volstead Law Violators Not Entitled to Protection on Cars

NEW YORK, Feb. 26—"Confiscation insurance" is forbidden to all insurance companies belonging to the National Automobile Underwriters Conference, by a recent decision of that body. As practically all the large stock insurance companies covering automobiles belong to the conference, this action means practically that it will not be possible to get insurance on an automobile against its being confiscated by the Federal government for carrying liquor in violation of the Volstead law.

Insurance underwriters have in general been of the opinion that violators of the Volstead law were not entitled to insurance; and that practically all innocent victims of confiscation already insured against theft would be able to claim indemnity on the ground that the car was stolen. Perhaps the only protection which could be asked of insurance companies was against misuse of the car by a friend.

But the underwriters maintained that if this were to be covered, every enterprising bootlegger would frame his case to correspond, with the result that insurance companies would find themselves betting against a bootlegger's risk of capture.

A recent ruling of a Federal court provides that automobiles "held for trial" may be taken out on bail, that is, for deposit with the court of collateral security. If an owner feels that his car is not likely to be confiscated, that he has an open and shut case, he can, under this ruling, provide care of the car to prevent deterioration.

Oldfield Tire Company Elects New Officers

AKRON, Feb. 25—J. M. Dine, former Firestone official, has been elected vice-president and general manager of the Oldfield Tire Co. Dine has been identified with the rubber industry for fourteen years, both with Goodyear and Firestone. He served as branch manager for both companies in several large American cities.

Other new officers of the company include B. M. Robinson, secretary; H. L. Allsopp, treasurer, and M. E. Moffett, assistant treasurer. R. S. Jemison, of the Miller Rubber Co., has assumed the position of advertising manager.

The Oldfield tire, comparatively a new product on the market, designed by Barney Oldfield, former champion of the motor speedway, won recognition during the 1920 automobile racing season. Mr. Oldfield has just moved central offices of the company to Akron from Cleveland, and announces plans for a material increase in production during current year.

Road Makers to Get 1250 Army Tractors

Senate Turns Down House Action for Dumping—Bill Goes to Conference

WASHINGTON, Feb. 25—Amendment to the Fortification bill, as passed by the Senate to-day after a heated debate, provides for the transfer of 1250 tractors from the War Department to the Department of Agriculture for distribution among State highway departments. The proposal to authorize the sale of 2000 tractors, as passed by the House, was voted down by the Senate. Majority leaders under the management of Senator Wadsworth of New York, chairman of the Military Affairs Committee, championed the efforts of the War Department to retain all tractors, but the will of other Senators, sponsored undoubtedly by demands of highway commissioners for new equipment, prevailed.

During the debate it was brought out that the Chief of Ordnance of the Army estimated that the stock of tractors on hand would serve ordinary requirements for a period of five years. Senator Wadsworth, Lodge and Smoot, Senate majority leaders, directed the attention of the Senate to the fact that every tractor transferred or sold on the open market would require additional appropriations in the next few years. Senator Wadsworth predicted that, for every tractor distributed to highways at this time, there would be requests for new appropriations. It was stated that the army owned 6700 tractors on Dec. 31, 1920, but this was later reduced to 6452, which are retained at present. The Army now has 3109 tractors in service, and the others are in storage at Rock Island Arsenal and at Savannah Proving Ground. According to the information given the chairman, the shelter provided is adequate and constant care is given the equipment.

Would Avoid Obsolescence

Democratic Senators suggested that inasmuch as there had been great improvement in design of tractors, it would be best to dispose of the surplus because of the obsolescence. Chairman Wadsworth stated that the balance of tractors were obligated but not assigned. He contended that the artillery continued to extend the use of the tractor in the transportation of heavy guns, as the average tractor will do as much as six horses and is maintined at lower cost. He said that artillery officers were confident that the use of the tractor would bring about a large saving. There will be another demand for tractors, Senator Wadsworth said, when the reorganization of the National Guard is completed.

The New York Senator asserted that the heavy tractors owned by the Army are not especially adapted to road uses and that no spare parts could be obtained on the open market. He pointed out that many tractor manufacturers who built these machines under specifications prepared by the War Department were not operating. According to information given Senator Kellogg of Minnesota, the War Department has never transferred any modern tractors. The Chairman ridiculed the legislative efforts of highway commissioners whom, he said, were flooding the Senators with telegrams urging the transfer. "It is all velvet for them" Senator Wadsworth said, "they get something for nothing and do not take cognizance of the War Department's future needs." The National Guard has until 1924 to complete the organization of new units and it will require hundreds of tractors for their use. With the authorization for transfer, it would indicate that the Army will be on the market for tractors within a year instead of five as expected. The Senate bill has been sent to conference.

Goodyear to Produce New Airplane Fabric

AKRON, Feb. 26—Wade Van Orman, aeronautical expert of the Goodyear Tire & Rubber Co., has designed and perfected a leak-proof, fire-proof rubber and fabric covering for airplane gasoline tanks, which has been formally accepted by the United States Government, Goodyear officials announce. The new cover will be extensively manufactured for the government, exclusively by Goodyear.

The cover, designed especially for combat and mail planes, consists of a specially vulcanized half-inch thick rubber blanket affixed to a thick layer of several plies of tested cotton fabric. It fits directly over the airplane fuel tank.

Tests conducted by the government at the Goodyear plant in East Akron have proven that when both the covering and fuel tank are punctured by bullets, the rubber and fabric cover automatically closes and completely seals the leaks, preventing leakage of fuel and subsequent explosions in mid-air. The cover will prove particularly effective in use on combat machines, where incendiary bullets are used in aerial engagements, government officials say.

The new cover is admitted by government aeronautical officials, to constitute a material step towards attaining a greater degree of safety than heretofore gained, in airplane transportation.

MAIBOHM ADDS DIRECTORS

SANDUSKY, OHIO, Feb. 28—Three additions were made to the board of directors of the Maibohm Motors Co. at the annual meeting. They are B. C. Kramer of Toledo; George M. Zimmerman, city manager, of Sandusky, and Hal Holtom. Kramer has been elected vice-president and the other officers of the company were re-elected. Reports showed that profits for the year, before taxes and reserves amounted to approximately 12 per cent on the outstanding capital. President Maibohm said there was a gratifying revival of business and that orders were increasing.

New York Modifies Truck License Plan

Abandons Proposed Prohibitive Rates as Impracticable—Will Pay Full Maintenance

ALBANY, Feb. 26—Though the proposed plan of taxing heavy duty motor trucks from the highways of New York has been abandoned as impractical, the State legislature is proceeding with its plan to enact laws which will place the entire burden of road maintenance upon car owners. Under the tax schedule embodied in a bill introduced today fees are boosted from 50 to 100 per cent.

Included in the provisions of the measure are increases in taxes of 25 to 40 cents per horsepower. Trucks of more than three tons weight are assessed double. On a tonnage of from two to three the tax is increased from $15 to $23.50; three to four tons the increase is from $20 to $40. The ten-ton truck will pay $110 and the tax on the 14-ton vehicle will be $140. For every ton in excess of fourteen, the tax will be $20.

The tax on trailers is raised from $5 to $7.50 where the weight is two tons or less, the increase being graduated up to the trailer weighing from ten to 14 tons, on which a tax of $60 is levied.

The tax on omnibuses with a capacity of five persons or less is raised from $15 to $22.50. Where the capacity is more than 30 passengers the tax is increased $67.50 to $101.25.

It is estimated that the new schedules will yield $9,000,000 a year, or $1,000 a mile for the 9,000 miles of State highways. About $6,000,000 was realized from car revenues in 1920. Automobile associations are planning to oppose the new rates unless changes are made in the system of administering highway maintenance.

BENDIX WINS PATENT SUIT

WASHINGTON, Feb. 26—The claims of Vincent Bendix for priority on the invention of an electric starting motor for internal combustion engines have been upheld in the United States Court of Appeals for the District of Columbia on appeals entered by Edward A. Halbleib, Frank Conrad and Joseph Bijur. In making its decision the court ruled that Bendix by reason of reducing his invention to practise before the appellants, established his right to priority.

ARABS BUY MOTOR VEHICLES

LONDON, Feb. 11—(*Special Correspondence*)—Reports are to hand of recent successful tractor trials lasting over 14 days in the Bagdad area of the Middle East. The Fordson was one of the number which showed up well. The Arabs appear to be progressively affected just now and are investing in motor cars, the Sheikhs even going to the cost of re-making suitable roads. The British army of occupation has this result to its credit.

Airplanes to Open Canadian Oil Field

Test As Rival to Steamers and Dog Trains to Come in Spring —Expect Rich Deposits

EDMONTON, ALTA., Feb. 25—The British Dutch Shell interests have purchased considerable holdings near the Fort Norman gusher struck by the Imperial Oil Co. of Canada, Ltd. (Standard Oil.) It is now said that the alleged 1500 bbl. per day output was a gross under-statement of production as the output of the Fort Norman gusher was about 6000 bbl. a day of the finest crude in gasoline content on the continent. However that may be, the Shell people are reported to have twelve outfits ready to move in when transportation is again possible.

The flat statement of the Federal government chief geologists that there is every reason to believe that in the basins of the Athabasca, Peace and Mackenzie rivers will be found the largest deposits of oil in the world coupled with the fact that the greatest oil interests are spending millions on development in the territory promises to result in a stampede north from here and other points, comparable to the Trail of '98, as soon as the snow barrier is broken.

The expected rush to the northern oil country this coming spring and summer has made transportation a big live question in the Canadian Northwest. After long service by dog teams, which hitherto have been sufficient for the purpose, flying machines, new steamers and railway lines are now proposed, for everybody wants to get there in a hurry.

If all the plans work out as now in prospect, there will be in the country between Edmonton and the Mackenzie River oil fields the greatest practical test of commercial aviation that has yet been attempted in Canada. Five distinct flying enterprises are proposed, all of them to be inaugurated, it is announced, this coming season. The Imperial Oil Co. already has two monoplanes on the ground, having flown them from New York under conditions severe enough to give a good hard test of winter flying, and in the early spring it will begin moving its own men and supplies into the north by the air route.

First Enterprise of Kind

This was the first enterprise of the kind, and was decided upon by the Imperial company entirely as a means of doing its own transportation work in the quickest possible time. The planes will fly between Peace River, which will be their base, and Fort Norman, and as far beyond as occasion may require.

The Canada Air Board is also understood to be planning a service into the north for the carriage of Dominion Government geologists, surveyors and scientists, who will be working in different parts of the wilderness country and well beyond the reach of other transportation service. It is claimed that there will be enough of such work to be done to keep an air service well occupied all through the season, and obviously enough it would enable a vastly greater amount of territory to be covered in the summer and autumn months than has ever been possible under the canoe-and-pack system.

F. G. Erickson, the Toronto and New York birdman, has announced his intentions of operating a flying service between Great Slave Lake and Fort Norman on a commercial basis. A Calgary company is already advertising for bookings for a flying boat line that is to begin in the spring between Fort McMurray and the Mackenzie oil fields, following in general the course of the northern waterways. But the most ambitious of all the schemes is that of Capt. E. L. Janney, of the Northern Canada Traders, Ltd., with whom is associated Major C. K. Wollan, of Los Angeles.

Dirigible to Carry 30

A dirigible capable of carrying about thirty passengers will be put on the Edmonton-Mackenzie route, according to Capt. Janney's plans, in March, and after a demonstration flight, on which a party of Canadian and American newspapermen are to be eye-witness guests, a quick service to Fort Norman and back is to be commenced. The fare will be $1500 for the round trip.

It is the expectation of these several flight masters that there will be a rush of oil seekers and sightseers into the north as soon as spring opens and all through the summer. That, indeed, is what everyone is looking for; but the most experienced northerners are hesitating to accept the theory that there will be enough doing in the oil country to warrant a stampede.

The reports of this expected boom have already been greatly overdrawn. It has recently been stated in the east, for instance, that 3000 prospectors are now in Edmonton waiting their time to move on into the north as soon as conditions will permit. Such an army of wealth-hunting waiters has never, of course, been even approximated, and if the plans of the airmen are not based upon better facts than this, their success will be questionable.

Round Trip Cost $1500

The commercial air routes to the north will naturally compete with the already established steamboat routes. As against the $1500 round-trip fare by airship, the steamboats carry for $300 from Fort McMurray to Fort Norman and return. The air route has, of course, a great advantage in point of time, as compared with one month by water. The cost by airship, as thus announced, is about the same as that of the long overland journey by dog-train. For the inexperienced man who undertakes a winter trip into the north, and who wants to go in comfort, two teams of four dogs each will be necessary, with three men, and the cost will run close to $1500 from Edmonton to Fort Norman and back.

Chile Seeks Funds for Highway Work

Plans Expenditure of 20,000,000 Pesos Annually—Bankers Approached on Loan

NEW YORK, Feb. 28—An estimated 20,000,000 pesos will be available yearly in Chile for road construction and improvement under the new highway law of that country. Confirmation of the final approval of this law, which became effective in July of last year, is contained in letters just received by EL AUTOMOVIL AMERICANO, the Spanish automotive magazine of the Class Journal. The normal value of the Chilean gold peso is $0.365, and the paper peso $0.2065.

The revenue estimate was made by F. Pesse Smith, of Puerto Montt, Chile, road director of the Chilean province of Llanquihue, who adds in his letter that this will mean an average investment of 2000 pesos per kilometer of road. The present highways of Chile, of which only a small percentage is in acceptable condition for traffic, total about 30,000 kilometers.

These roads will be improved and maintained under the new law either by permanent or semi-permanent surfacing. The cost of a permanent surface is estimated at 20,000 pesos per kilometer. Furthermore, according to these advices, the government has under consideration a loan of 200,000,000 pesos so that it will be possible to improve a large portion of the highway system in a very short time. New York bankers have been approached on the subject of a Chilean loan and it is probable that it will be one of the Latin-American republics to receive financial consideration.

Director Smith is desirous of obtaining data on road building machinery, etc., his letter stating:

"It is of interest to us to be posted concerning the proper machinery for building highways, rock breakers, concrete making machines, compressing rollers and, generally speaking, all kinds of machinery which is efficient in the economical construction of highways."

WOULD CONTINUE DEFENSE WORK

WASHINGTON, Feb. 28—Organizations interested in the promotion of industrial research and economic movements have been attempting to convince Congress that the Council of National Defense is necessary for national welfare. The Council has several studies relating to automotive enterprise and highway development. This work will be dropped in June unless Congress appropriates a sum sufficient to maintain the present organization. The Council commenced an inventory of automotive resources and is sponsoring a standardization campaign based on their findings in this inquiry as to specifications. At present they have under consideration the encouragement of the use of chassis and other automobile parts which would be easily converted for war purposes.

Sales Tax Opposed by U. S. Chamber

Against Substitution for Excess Profits Levies—Special Tax Favored

WASHINGTON, Feb. 28—Representatives of the automotive industry who have felt that there was little probability of Congress levying additional excise taxes and that there would be a widespread demand throughout the country for some form of sales tax as a substitute for imposts which now are unpopular, will find cold comfort in the report of the committee on taxation of the Chamber of Commerce of the United States, recounting the results of a national referendum on 15 proposals for changes in the present taxation system.

There was an almost unanimous demand among the members of the chamber for a repeal of the excess profits tax but THERE WAS A MAJORITY VOTE AGAINST ANY FORM OF SALES TAX SUGGESTED BOTH AS A SUBSTITUTE FOR AND IN ADDITION TO OTHER FORMS OF TAX. The proposal that excise taxes should be levied "upon some articles of wide use but not of first necessity," partly to take the place of the excess profits tax, was carried by more than a two-thirds vote. The ballot on this question stood: For 1217; against 504.

On the question, "should a sales tax be levied instead of an excise or excess profit tax," the vote was: For 704; against 855. Those who favored a retail sale tax and those who favored a general turnover tax were about evenly divided.

The committee submitting the report opposed the sales tax but put the proposal to a vote because of the wide interest manifested in a levy of this nature. The vote against this tax is significant in view of the strong agitation throughout the country in favor of it.

N. A. C. C. Records Preference

The National Automobile Chamber of Commerce is the only organization connected with the industry which has gone on record formally in favor of a sales tax although the Motor & Accessory Manufacturers Association and the Rubber Association of America are in favor of a sales tax, though not on retail sales as proposed by the N. A. C. C. The proposal of Secretary of the Treasury Houston, that the excise tax on passenger automobiles be doubled is strongly favored by many of the Congressional leaders and members of the United States Chamber of Commerce who voted in favor of such action did so with the understanding that excise taxes levied should be supplemental to those now in effect.

There is a strong sentiment in Congress against any form of sales tax. The professed belief among senators and representatives is that if a 1 per cent tax on sales were authorized, many unscrupulous dealers would use it as a means of bringing in additional profit by adding to their prices several times the amount of the sales tax. This, it is feared, would arouse resentment among the ultimate consumers who always pay the taxes in the last analysis and would result in the loss of votes. Advocates of the sales tax contend on the other hand that consumers would suffer less from the sales tax than they would from any other form of levy.

Government Committee to Standardize Fuels

WASHINGTON, Feb. 25—In accordance with instructions of President Wilson, an Interdepartmental Committee on Standardization of Petroleum Specifications has been organized to supersede the wartime organization, which had for its purpose the purchase of improved motor fuels and lubricants and the conservation of natural resources through more efficient utilization of petroleum products. The activities of this committee have a direct influence on the quality of petroleum products used in the automotive industry inasmuch as Government standards are accepted in the trade.

The President stated that the function of the committee is to prepare and adopt specifications for supply of petroleum and its products to any and all Federal departments and revise such specifications when the need arises giving due consideration to the amounts and qualities of crude petroleum available. Representatives of the Society of Automotive Engineers participated in recent conference when the new specifications were accepted.

Fuel Reserve Stocks Increase in December

WASHINGTON, Feb. 25—Reserve stocks of gasoline continued to increase during December despite extensive use of automobiles permissible with mild weather. Refinery statistics compiled by the Bureau of Mines show that the daily average production for December was 14,980,431 gal., or about 107,000 gal. less per day than in November, but 4,000,000 gal. more than daily average for December, 1919. Stocks advanced 108,000,000 gal. over November.

At the close of the year there were 462,381,837 gal. of gasoline in reserve at refineries. This figure is equivalent to the entire production for the month showing a marked decrease in consumption. Production of lubricating oil increased the reserve by 18,000,000 gal. over the stocks held in November. The 328 refineries operating during December had a daily capacity of 1,714,395 bbl. of crude oil.

HAYES RESUMES OPERATIONS

ST. JOHNS, MICH., Feb. 25—Hayes Wheel Co. will begin operations with a full force Tuesday, building truck wheels. The plant was closed in December and no operations have been attempted since that time.

Mellon Expected to Ease Tax Load

Industry Looks for More Conciliatory Attitude—Congress Misinformed on Conditions

WASHINGTON, March 1—Andrew W. Mellon, Pittsburgh banker and new Secretary of the Treasury, looms as a new and formidable factor in taxation matters relating to the automotive industry. The next Congress will take under advisement his recommendations as to means and methods of raising revenue. Congressional leaders in charge of the fiscal program say that this action does not imply that the Houston program will be discarded. On the contrary the utmost consideration will be accorded the retiring Secretary's proposals because they are founded on an intimate knowledge of the country's fiscal requirements.

Chairman Fordney of the House Ways and Means Committee advised AUTOMOTIVE INDUSTRIES that he was personally opposed to imposing a two cent a gallon tax on gasoline because it was obviously iniquitous. He stated that the intention of Secretary Houston and his tax advisers was undoubtedly based on an attractive theory in specifying that the tax should be levied at the refinery instead of distribution station. The chairman contends that the oil companies would find a way out and transfer the tax to the consumer, particularly the automobile owner.

Mr. Fordney's time has been absorbed so completely in study of tariff legislation that he has devoted little attention to the Houston program. He declared that he would inquire into the effects of an additional excise tax on automobile manufacturers and the proposed horsepower tax at an early date.

Senator Penrose and Senator Smoot, the most influential figures in the Senate Committee on Finance, have not inquired into the Houston plan in detail because of the pressure of other legislative business at the last session and the knowledge that internal revenue legislation would not be considered until the extraordinary session.

Tax Hearings to Come Soon

Senator Townsend of Michigan, who has a deep interest in the welfare of the automobile industry because of its influence on the welfare of his State, told AUTOMOTIVE INDUSTRIES that the Senate would probably take up the taxation problem within a few weeks. He pointed out that it was customary for the House to inaugurate tax legislation and the Senate use its drafts as a guide.

The fact that the new Secretary of the Treasury has an inside knowledge of the financial conditions of the automotive trade, due to his relations as a banker, is expected to influence his recommendations. It is stated that Mr. Mellon knows that the imposition of an

(*Continued on page 532*)

Ford in Interview Declares Optimism

January Sales Establish Record—Starts Tractor Output—Wage Scale Continues

(*Continued from page* 524)

and more willingness to give the best that is in them, the volume of labor required for a given task can be reduced greatly. Our office force today practically is what it was under pre-war conditions in 1914."

When it was suggested that production of 2860 cars yesterday with a force of only about 16,000 was extraordinary, Edsel Ford offered the explanation that much of the machining of material had been done prior to the shut-down in December and in consequence production with the minimum force was made possible.

Regarding reports of a car surplus of 125,000 at the time the plant shut down Mr. Ford said there were no finished cars save 95,000 in the hands of dealers and 30,000 in transit and in process of construction at the assembly branches, construction of which was completed during January. During the same month, he said, retail sales were 57,000, materially reducing the surplus which he said rapidly was being liquidated by constantly increasing sales.

Turning to W. A. Ryan, Mr. Ford asked if January sales had not established a record for that month and Ryan replied that no actual comparison had been made but that the total was probably a record.

With the ratio of sales continuing, Mr. Ford said, cars now held by dealers soon would be in the hands of consumers necessarily compelling an increase in output to meet current demand.

The Highland Park plant builds finished cars for Michigan and a part of Ohio and builds all engines and other mechanical parts which are shipped to the branches daily for assembling. The total built in the main plant and branches constitutes the daily output, with the Highland Park plant turning out about 350 cars as its quota.

2700 at River Rouge Plant

Repudiation of the many reports concerning Ford activities is emphasized not only in operations in the Highland Park plant but in the actual reopening today of tractor production at River Rouge where a force of 2,700 is employed, manning the blast furnaces, building tractors and working in various capacities. Although the Rouge plant never had been closed, Mr. Ford said. production of tractors had been stopped pending completion of preparations for resuming manufacture by the new system of pouring iron put into effect today.

Mr. Ford appeared particularly pleased to respond to the question regarding reported cuts in wages among his employees.

"There has been no reduction in the wages for specific jobs," said he, "and there has been no reduction in the minimum wage scale. Many foremen and other employees who had been working at higher wages were given opportunity to accept employment on other work at the prevailing scale for the particular job. The effort to minimize hardships by giving them part-time work even though it required their accepting wages lower than they had been paid on their regular work apparently was appreciated."

In voicing his optimism and full confidence in the future of the automobile industry Mr. Ford said:

Must Bring Back Normality

"The war and the unusual activities connected with it followed by the abnormal conditions accompanying the readjustment period brought about an unusual situation in the matter of labor and production and while everyone was for a time swept along on the tide of extraordinary industrial activity it easily was apparent that return to normal must be brought about by curtailment and readjustment all down the line. January was the breathing spell with the Ford Motor Co., following the period of intensive effort. We are all optimists out here and the figures given you are the best evidence that conditions are improving and that a brighter business outlook is becoming increasingly apparent."

On the question of successors to the men who have left the Ford organization, Mr. Ford suggested it was of little consequence who might look after the various activities of the company so long as the combined effort served to develop and promote its policies and ideals. Waving his hand at the group of executives about him he said:

"These men are all a part of this company. They are all financially interested to the limit allowed by the company under its investment certificate system. Let us eliminate the personal equation. This is not a Henry Ford organization but rather every executive and workman is financially interested in the welfare and future of the company. Why Edsel owns 43 per cent of the stock of the Ford Motor Co."

It was demonstrated plainly throughout the interview that the matter of titles for department heads or executives was of minor consideration and in fact there seemed to be an inclination to eliminate titles in most instances with matters of policy and efforts of all departments to be directed through conferences of all executives.

To Divide Responsibility

Mr. Ford's reply to a question as to who would be delegated with authority to reply for the company to questions that develop was significant.

"All of us," said he with a smile as he indicated the entire group, the inference being that all questions must be put to the executive conference.

Throughout the interview Mr. Ford maintained an air of composure, smiled constantly and never appeared ruffled even when questions regarding the many attacks and rumors were put to him.

GRADUAL INCREASE IN CAR MANUFACTURING BRINGS RELEASE OF HELD-UP PARTS ORDERS

NEW YORK, March 1—Better business is coming in the automotive industry. In fact it already has arrived. The pulse of life is stirring in all its branches. The stimulus of increased sales at retail has worked back at last to the car manufacturers. They are moving cautiously, but they are swinging into production. There has been no big splurge about it and there is no false optimism, but there is no mistaking the tone of the market.

The evidence is unimpeachable. It comes from the parts makers who supply the manufacturers of complete vehicles. They are getting some new business, but better than that, they are receiving an increasing number of "releases" on orders which have been held up since the slump began. These "releases" do not run into huge sums, but they show that the dam has been broken and they are beginning to turn into money some of the materials on hand for months.

Individually these orders are not large, but they bring with them reports of production in plants where there has been none before and of increased output in factories which have been doing some business. Most of them are for delivery this month. Numerous parts plants which have been running at 20 per cent of normal will double their output in the near future as the result of this business.

Collections are no worse than they were, and in some cases they are better. This is true especially of houses which deal directly with automobile dealers, and shows better selling at retail. There are many reports of motor vehicle manufacturers who have been hanging on gamely and whittling down their indebtedness as rapidly as they could work down their inventories and dispose of their products. Frozen credits are being thawed out gradually.

Most of the orders are coming from passenger car manufacturers, but there is some improvement apparent even in the truck field, where business has been virtually dead.

Parts manufacturers are giving earnest consideration to the question of prices. Many of them already have cut the prices of their own products and feel strongly that the prices of motor vehicles must come down before the market can be entirely stabilized.

Buffalo Interests Aid Dunlop Company

Company's Position Here Safeguarded—Will Need New Capital in Spring

LONDON, Feb. 12—(*Special Correspondence*)—The following statement in reference to the American interests of the Dunlop Rubber Co., Ltd., was made by F. Alexander Szarvasy, chairman of the board, at a general meeting of the stockholders today:

"Reference has been made on several occasions in the past to this undertaking, and you were informed that a company called the D. A. Trust had been organized, that £3,000,000 had been subscribed through the Dunlop America Pool, and that the home company had subscribed £1,000,000. The whole of this £4,000,000 was intended to form the Ordinary share capital of the American company, and it was understood, although I am advised that no binding agreement exists to that effect, as terms could not be agreed upon at the time—that the financing of the American company would be independently completed.

"Due, no doubt, to the abnormal financial conditions prevailing in America and in this country during the last quarter of 1920, your board was informed in October last that the proposed financing could not be carried through, and it was then that the problem arose whether it would be better to leave the American company to its fate, write off the £1,000,000 which had been invested, and risk the name of the Dunlop Company falling into disrepute, and at the same time run the further risk of some competitive company in America acquiring the partly built works, together with the name Dunlop, which would have meant competition against the home company, with its own trade mark practically all the world over. Most anxious consideration was given to this subject, and it was decided to remit the sum of £806,000 in order to avert receivership, and to give time for further negotiations.

Directors Visit America

"As I have already mentioned, two of your directors proceeded to America, and as a result of their efforts, arrangements have now been made whereby a bond issue of $6,000,000 has been created, secured on the American company's works and undertaking, the bonds to have a year's currency, to bear interest at 8 per cent per annum. The home company has undertaken to see these bonds funded at the due date. Four million, five hundred thousand dollars of these bonds were subscribed by local interests and local bankers at Buffalo, and $1,500,000 by the principal Ordinary shareholders in the Dunlop America Co., including the home company. With this additional finance the position in America has been safeguarded, but further working capital will be required after the completion and equipment of the mills—possibly to the extent of another six million dollars, or maybe somewhat more.

"The intention is to arrange this finance in America early in the spring by a bond issue of 12 to 14 million dollars, out of which the existing $6,000,000 bonds are to be redeemed and the working capital provided. It is intended that the home company should give its guarantee, if required, as to principal and interest on this bond issue, and it is partly for this reason that the amendments in the memorandum regarding powers of guarantee are being asked for.

"The home company is taking a risk in allying itself so closely with the American enterprise; it has been, however, a question of balancing one risk against another, and it would appear that the lesser of two has been chosen. It is part of the programme to offer to the D. A. Trust shareholders shares in the Dunlop company in exchange for their D. A. Trust shares; then the home company ultimately stands possessed of the whole of the equity in the American company, and thus be justified in giving its guarantee as outlined. If the American business is a success—and I am told that there is no reason why it should not be a very great success—it will be a most important source of revenue to the home company."

SECRETARY OF NAVY LEADER IN INDUSTRY

DETROIT, March 2—Edwin Denby, who will be secretary of the navy in the Harding cabinet, has been connected actively with the automotive industry since 1909 when he joined the Hupp Motor Car Corp. as a director and treasurer. He continued in that capacity until he enlisted in the Marine Corps at America's entry into the war in 1917.

He and Garvin Denby, organized the Denby Motor Truck Co. in 1914 and Edwin became its first president. He was succeeded as president of this company by A. S. More in the summer of 1920, but remained a director and holds the position of vice-president. He was active in the direction of Denby truck affairs, resigning as president to become a candidate for nomination as governor of Michigan.

WEST VIRGINIA BUYS CARS

CHARLESTON, W. VA., Feb. 28—Retail sales of automobiles were stimulated in this city by the automobile show. This section has not been so hard hit as many others by the industrial depression and the outlook is good for the coming year because Charleston's industries are diversified. As a matter of fact, the city is growing more rapidly than it ever has before. The population includes many persons of wealth and there is a good market for high priced cars.

Mellon Expected to Ease Tax Load

Longworth Bill to Sound Sentiment of Manufacturers — Many New Bills Likely

(*Continued from page* 530)

additional tax bill of $290,000,000, as contemplated by his predecessor, would be disastrous and tend to disturb economic conditions generally.

The Longworth bill, which will be reintroduced at the next session, is the "smoke screen" for the House Committee of Ways and Means, of which Congressman Longworth of Ohio is a ranking member. Chairman Fordney admits that the bill is intended to sound sentiment and obtain a better understanding of the effect such measures would have.

Even the most optimistic legislators admit that the Longworth plan for revising the revenue laws would not yield adequate sums. It is estimated that a levy on corporations, as proposed, at 15 per cent could not yield any sum in excess of $1,200,000,000. The Ways and Means Committee think that higher tariff duties would probably bring about $750,000,000 into the Treasury, though this total is apparently exaggerated considering the reduction in imports when higher rates are imposed.

Chairman Fordney and many other Congressional leaders have indorsed a movement to combine the tariff and internal revenue bills for the purpose of economy. Just what course will be taken in regard to fiscal legislation will be determined by President Harding after conferences with Senate and House leaders. With a changed personnel in the Senate and House, it is likely that many new tax proposals will arise.

One of the outstanding features of an inquiry into private opinions held by legislators as to tax proposals relating to the automotive industry is the misunderstanding that exists as to the real condition of the trade at present. There are many legislators who believe that the automobile industry has grown to such enormous proportions in a relatively short period that it is in a position to bear the brunt of taxation.

Congress Short on Figures

No better evidence of the menace which remains in the unchallenged theories is needed than statements of Senate and House leaders as to suggestions they have received as to revenue legislation. One legislator submitted a proposal to a committee chairman based on information he obtained in a newspaper, but did not verify. He told the chairman that by imposing a national tax of $2 per car, the Government would receive $1,600,000,000, based on a statement which he accepted that there are 800,000,000 motor vehicles in the country. His error was quickly pointed out by mention of the fact that these figures would give every inhabitant of the United States about eight machines.

Miller Dividend Is Carried Over

Charge Off of Merchandise Shrinkage Absorbs Earnings and Causes Deficit

AKRON, March 1—For the first time in its history the Miller Rubber Co. passed a regular preferred dividend today. Action of the company's directors in deferring declaration of the quarterly cumulative 2 per cent dividend on preferred stock due March 1, followed announcement that the company, despite a substantial increase in sales in 1920, had a deficit of $735,016 on Dec. 31, 1920.

Miller sales for 1920 were $32,891,670. This was an increase of approximately $5,775,082, or 21 per cent over sales for the previous year.

In notifying preferred stockholders of deferment of the dividend payment, officials of the company said:

"In closing the books for the year 1920 it has been deemed advisable to give full effect to, and charge off, the entire shrinkage representing the difference between the cost to the company of raw materials on hand and the market value of the same, and also to the reduction in value of in process and finished merchandise on hand, based on lower material, labor and overhead charges, as well as settlements for the cancellation of certain rubber contracts. The shrinkage in inventory on this basis aggregated $3,193,086 and payments made in settlement of contracts amounted to $215,951 for an aggregate of $3,409,037. This action resulted in a net loss for the year of $617,878, the net profit of the company prior to the charging off of the items referred to amounting to $2,791,158. It should also be stated that this profit was practically all earned in the first six months of 1920."

The company on Dec. 31, officials state, was obligated on unfilled purchase contracts for raw materials, the aggregate purchase price of which was $1,500,000 above the market price prevailing on that date. The portion of this which will result in final loss to the company is said to depend on the basis of final adjustment or liquidation of these purchases.

The company has current assets of more than $14,000,000, based on the conservative valuation of the inventory. Of these assets approximately $2,000,000 is in cash on deposit. The total current liabilities are listed at $8,676,000.

Goodyear Stockholders Indicate Preference

AKRON, Feb. 26—Less difficulty is being experienced in gaining the consent of the Goodyear Tire & Rubber Co. stockholders to the company's refinancing program involving $85,000,000, than was encountered in securing ratification of the original plans which involved only $50,000,000, officers of the company have announced. Proxies are coming in slow, however, and may necessitate an eleventh hour postponement of the stockholders meeting now set for March 4.

Inadequate post office facilities at Akron are held responsible by Goodyear officials, for the fact that proxies are coming in slowly. It was found that many of the registered letters containing notices and proxy blanks, issued to Goodyear stockholders, were held at the Akron post office for nearly a week before being distributed for delivery.

Proxies already received, however, indicate a readiness upon the part of stockholders to give the company a vote of confidence by ratifying the refinancing plans, Goodyear officials say.

Templar Opposition Fails to Materialize

CLEVELAND, March 2—N. P. Clyburn, chairman of a minority stockholders' committee, was represented at the meeting of stockholders of Templar Motors Corp. to-day by F. S. Monnett, but, according to President M. F. Bramley, had proxies representing less than 1 per cent of the stockholders.

The board of directors was re-elected with one exception, that being the replacement of A. M. Dean, chief engineer of the company, for Attorney John Orgill. Others elected were W. M. Pattison, W. O. Cooper, D. C. Reed and M. F. Bramley. The organization meeting will take place later.

President Bramley said the company sold 40 cars in October, November and December, 20 in January, and 68 in February, and that orders have been taken for 162 for March and April delivery.

"We have 350 cars finished and 350 in process of construction," Bramley said last night. "We are employing 165 men of a normal number of about 900."

Discontinue J. L. Planes Pending Investigation

WASHINGTON, March 1—Coincident with the House resolution directing the Postmaster General to submit complete information as to the purchase and operation of Junker planes in the air mail service the Post Office Department advised AUTOMOTIVE INDUSTRIES that they had discontinued the use of the J. L. planes until additional tests could be made to determine their mechanical imperfections. It was also stated that the air mail service had employed engineering experts for improving and standardizing the Liberty motors which are now used almost exclusively by the service.

CREDITORS DIRECT PREMIER

INDIANAPOLIS, March 1—A new committee of creditors has virtually taken charge of the affairs of the Premier Motor Corp. This committee is headed by B. L. Craig of the R. M. Collins Co. of St. Louis. The other members are B. H. Miller of the American Foundry Co. of Indiana, and C. B. Reynolds of the B. F. Goodrich Co.

Keystone Tire, Buyer of A. E. F. Surplus

Practically All of Stock of 350,000 Tires Purchased—May Impose Excise Tax

NEW YORK, March 2—Through information released by the Under Secretary for Liquidation of Stocks of the French Government, it is learned that all but 12,800 tires of the 350,000 A. E. F. surplus has been bought by the Keystone Tire & Rubber Co. of this city. Information was declined at the Keystone offices here as to the number which have been already returned to the United States or as to the sizes of the tires.

Of the total of 337,200 tires bought by the Keystone company, about 200,000 are pneumatics and 150,000 solids. They are all of standard makes, and the pneumatics, for the most part, are said to be odd sizes. Information on the number of tires involved in the sale was obtained by the Rubber Association from the American Ambassador in Paris.

It is understood that no excise tax was imposed on these tires at the time of sale to the War Department and that action will now be taken to assess this.

N.A.C.C. Offers $5000 for Essays on Safety

NEW YORK, March 3—Prizes totaling $5000 will be offered by the directors of the National Automobile Chamber of Commerce to school children for the best essays on the prevention of street accidents in which automobiles are involved, as part of a national safety campaign in which the chamber will cooperate with the Playground Association and the National Safety Council. Appropriation of the prize money was made at the directors meeting yesterday.

Reports on car shipments showed an increase of 50 per cent for February over January. February shipments were 33 per cent of February 1920 shipments. Reports received from dealer organizations in 20 sections of the country indicated that February was the best month since September. The outlook for March and April was pronounced better yet. Used cars were reported selling but at sacrifices in price.

WEED CHAIN PATENT UPHELD

WILMINGTON, DEL., March 1—In the suits of the American Chain Co. against the United Auto Stores, Inc., Judge Morris in the U. S. District Court here, entered the final decree Feb. 25 holding Weed patent No. 768495 of the reversible chain grip to be valid and infringed by the grips made by George J. Campbell and sold by the United Auto Stores. It was also held that the infringing grips were finished in a style or dress that so closely imitated the weed grips made by the American Chain Co. as to constitute unfair competition.

Export Shipments Continue to Gain

January Shows Drop in Cars and Trucks but Parts Consignments Increase

WASHINGTON, March 1—Foreign trade in automotive products as a whole showed a marked tendency toward expansion, according to statistics prepared by the Bureau of Foreign and Domestic Commerce on International trade during January. While demand for passenger cars and trucks fell off slightly as compared with January of last year, shipments of automobile parts, not including engines and tires, doubled. There were unmistakable evidences of a stimulated demand for foreign cars on domestic markets, as the record shows that fifty-four automobiles valued at $94,653 were imported during January, 1921, as against thirteen cars and a valuation of $28,694 in the corresponding period last year.

Totals for the seven months ending January, 1921, indicate that the cultivation of foreign markets is quite successful and, that based on the showing for seven months, exports of automobiles and trucks will reach unprecedented proportions by June 30. There has been a curtailment in the demand for automobile and marine engines, but this decrease has been to a large extent offset by substantial increases in exports of stationary and tractor engines. One of the noticeable developments of the foreign trade for January was the heavy demand for American motorcycles.

As to imports and reimportation of automobiles, the official figures show that foreigners are gradually finding a market for their products in this country. For the seven months of the present fiscal year ending January, there were 860 cars valued at $905,093 imported, as against 97 cars with a valuation of $137,636 for the corresponding period in 1920. Imports of automobile parts increased in about the same proportion. The value of these imports for the seven months ending January, 1921, was $860,122, as compared with $286,589. In January, 1920, automobile parts imported were valued at $34,191, while for the same month this year they increased to $93,841.

Creditors Committee to Confer With Apex

YPSILANTI, MICH., March 1—Creditors of the Apex Motor Corp. to the number of 35 have selected a creditors committee to handle the accounts owed by the corporation in behalf of creditors by such agreement as the committee can enter into with officials of the corporation. The committee is headed by John French, president and general manager of the Michigan Stamping Co., Detroit; W. E. Hobell, treasurer of the Franklin Press, Detroit; Andrew Hochstrasser, of the Warman Brass & Aluminum Co., Cincinnati; E. F. Goodwin, cashier First National Bank, Ypsilanti, and M. M. Reed, president Ypsilanti Savings Bank. The five committee men represent the largest amounts owed by the corporation.

The committee was empowered by creditors assembled to act for them in extending further time for the payment of debts, and to act with corporation officials in working out an agreement.

Bethlehem Stockholders Find Position Serious

ALLENTOWN, PA., March 2—Affairs of the Bethlehem Motors Corp. are declared discouraging by the stockholders' committee after an investigation of the affairs of the company. The statement of the committee follows :

"The committee has examined a 'report on examination of account' of Aug. 25, 1920, and this report and information which has been obtained from other sources is most discouraging. Assets taken over by the receiver for the company consist of total assets of $4,396,707, of which $2,685,567 are considered current assets. Total liabilities, all of which are current, are $3,222,544.

"Seriousness of the situation from viewpoint of stockholders is indicated by an analysis of the statement. The corporation's liabilities amounted to $3,322,548, against which is had only $620,963 of readily liquid assets. Value of inventory (which under recent and present condition of automobile industry must be regarded as far from readily liquid) was $2,064,003. Accepting the inventory at that figure and assuming it to be readily liquid, current liabilities exceed current assets by $536,977.

"The committee frankly states that in face of the figures the situation is discouraging, but it is not without hope that if conditions in the industry change for the better and proper management and adequate working capital can be obtained, a reorganization or adjustment can be had which will materially improve the present situation of the stockholders."

Kissel Drops Equipment and Lowers Price $700

HARTFORD, WIS., Mar. 1—by using wood wheels instead of wire wheels, eliminating the bumper, snubbers, clock and some minor articles, the Kissel Motor Car Co., has been able to place the De Luxe touring car minus the De Luxe fittings on the market for $2775 which is $700 under the price of the more elaborately fitted model. All other details remain as before.

BRISCOE TO TAKE INVENTORY

JACKSON, MICH., March 1—Briscoe Motors Corp. will be closed for approximately 10 days for the purpose of taking the annual inventory, Feb. 28 being the closing of the fiscal year. In making the announcement officials took occasion to emphasize that the shut down merely was for inventory purposes and in no sense due to lack of business.

Parts Service Cuts Profits of Dealers

Truck Makers Fear Limiting of Business to Sales—To Confer Further

CHICAGO, Feb. 25—Representatives of the Motor Truck Manufacturers Association and parts and unit makers met at an all-day session at the Hotel La Salle yesterday to discuss the question of service and distributing stations which the manufacturers of parts and units have been establishing throughout the country and which, it is felt, will affect more and more as time goes by the business of the truck dealer.

The discussion brought no tangible results though it indicated that there is very little disposition on the part of the parts and unit makers to relinquish the ground they have already gained or to stop from continuing to establish stations with the ultimate view of twelve hour service. It is expected that they will adopt a program of future procedure in the matter of opening up new territory and will submit it to the truck manufacturers for suggestions.

The invitation for the conference was extended by the truck association and was accepted by a large number of the parts and unit makers who either have already established stations or are contemplating doing so. New phases of the situation are continually cropping out, making a satisfactory solution of the problem equally difficult for both branches of the industry. The difficulties will be settled at conferences.

Individual service and distributing stations for parts and units were started by the makers several years ago, but not until recently has the expansion been so great as to cause the truck manufacturers to take action. Now there is a determined move on the part of the manufacturers to do something that will meet the situation.

Would Combine Stations

There are indications that in cities where one part is being handled by a parts maker distributer, this same distributer will take on the product of some other parts maker, thus doing away with a multiplicity of parts station in any one community. The expansion of such stations necessarily will affect the regular truck station handling service, for where a part can be purchased from a parts station direct service will be done either at that station or at a repair shop nearby in cases where the parts distributer does not handle service.

Such a condition will mean that the truck dealer or distributer service station will find its profits from the service end of the business considerably curtailed unless some arrangement can be effected whereby as complete a stock of parts can be carried as that carried by the parts distributer and that the dealer or distributer of trucks will find his sole business to be in selling trucks.

INDUSTRIAL NOTES

Atlas Wheel Co., Cleveland, is to erect a new factory that will have a maximum capacity of 3000 wheels per day. The present plant of the company has been outgrown. Announcement about the new factory was made at the annual meeting of stockholders. Directors re-elected were: H. P. Arnt, David D. Walker, H. A. Duetemeyer, E. S. Reed, E. E. Ledeger, M. McC. Everhard and E. A. Fischer. Arnt was chosen president, Everhard vice-president and Walker treasurer.

Nash Motors Co. is starting work this week on the construction of another machine shop unit of its new four-cylinder car division works in Milwaukee. The main shops were completed late last fall and the plant is now in operation on a regular schedule. The present work is a continuation of the original plans of the Milwaukee plant project, which will cover about two years of construction work.

Packard Electric Co., manufacturers of Packard transformers and Packard starting, ignition and lighting cable, has moved its New York offices to the Printing Crafts Bldg., Eighth Avenue at Thirty-fourth Street. J. Ed. Erickson, manager for the New York district, is in charge.

Robertshaw Mfg. Co. has moved the sales office of the industrial department from New York to the factory at Youngwood, Pa. W. D. Crouch, sales manager of the industrial department, has been made general sales manager over both the industrial and domestic departments.

General Motors Corp. will change the name of the new Durant Building, Detroit, to the General Motors Building. W. C. Durant has resigned as president and director of the Durant Building Corp. and A. P. Sloan, Jr., has been chosen to succeed him.

Apple Electrical Mfg. Co. has been organized in Dayton, Ohio, with a capital of $500,000 cumulative preferred stock and 5000 shares of common stock of no par value, to manufacture a line of dynamo-electrical machinery.

Consolidated Instrument Co. has been formed with offices in New York, to render service in connection with all types of speed indicating and recording instruments and devices.

Kant Kut Tube Products Co. has been organized in Indianapolis to take over the ignition wire tube department of the E. C. Atkins Co.

Cutler-Hammer Mfg. Co. held a general sales meeting in Milwaukee Feb. 14 to 19, which was attended by all district office managers.

Stewart Mfg. Corp., Chicago, has opened a permanent Cleveland office under the management of E. P. Grismer.

Grant Motor Car Corp. announces that it has discontinued the building of trucks indefinitely.

Calumet Truck Body Corp. will name its new product the Calumet All-Purpose Truck Body.

LIBERTY STARTER RESUMES

DETROIT, Feb. 25—Liberty Starter Co. which makes the majority of starters for Ford cars and which has been closed more than two months, has reopened with a few hundred men and the force will be increased steadily until a maximum of 750 is employed, this total representing about 50 per cent of the normal force. A five day week schedule will prevail at the plant for the present.

"We will ask the men to give us their best efforts and there will be no cut in wage," said President Hartwig. "The five-day week plan will be maintained until increased business justifies a full week."

Stewart-Warner Raises $2,000,000 New Capital

CHICAGO, Feb. 28—The Stewart-Warner Speedometer Corp. has sold to the Central Trust Co. of Illinois $2,000,000 of 8 per cent five year convertible bonds to finance the purchase of the business of the Van Sicklen Speedometer Co., to pay bank loans which amounted to $200,000 on Dec. 3, and to reimburse the treasury of the Stewart-Warner Corp. for improvements made in the last few years from surplus and earnings. The bonds will be convertible into Stewart-Warner stock at $40 a share.

The products of the Van Sicklen Speedometer Co., which is of the air type, will add variety to the Stewart-Warner line which is of the magnetic type. This is the second competitor taken over. The Warner Instrument Co. was acquired in 1912, the consolidation forming the basis for the present corporation.

New Air-Cooled Car for Fall Production

PHILADELPHIA, Feb. 25—The newly organized Fox Motor Car Co., whose president is Ansley H. Fox, head of the A. H. Fox Gun Co., will open its plant at Tabor, next week. The factory has 100,000 feet of floor space and improved machinery and equipment. It is expected that the new car will be placed on the market in the fall. It is planned to produce no less than 2000 cars the first year. The Fox car will be new in design, embodying an air-cooled system. The price of the touring car will be $3500.

Ansley H. Fox maintains an office at Broad and Huntingdon streets. Louis E. Fifer is secretary. The directors are the foregoing and S. M. Germane, Colonel Sheldon Potter, formerly director of Public Works of Philadelphia; Budd G. Nice, Frank H. Schrenk, M. A. Sherritt and Walter J. Rice.

INDEPENDENT TO MAKE TRUCK

YOUNGSTOWN, OHIO, Feb. 28—The Independent Motor Truck Co. announces that it will get into production soon on a 3½-ton vehicle which has passed all tests satisfactorily. The company has been in process of development for three years and now has a capitalization of $1,000,000. A recent combination has given it control of two truck body factories and it is expected other units will be added in the near future. It is understood that a speed wagon to sell around $1500 will be put out in the spring.

METAL MARKETS

IRON and steel prices continue in the twilight zone. Sagacious automotive purchasing agents, however, are not permitting the numerous smoke screens that make for still lower visibility to warp their judgment of market conditions. Newspaper reports "play up" daily price cuts by this or that producer when, in fact, such cuts do not represent new reductions but merely signify that the individual interest named has fallen in line with the price levels previously established by other "independents." Because of its cumulative character this sort of publicity tends to create the impression that the market has declined to much lower levels than it really has, and to enhance the danger of an unnatural rebound in prices. Prices for steel are still more than double what they were in 1914, although 27½ per cent below those prevalent a year ago. There is a disposition among sheet rolling mills in the Youngstown district to make concessions for second quarter deliveries, the general anticipation being that there will be a sharp reduction in the wage schedules of sheet mill workers for the March-April period. After all, however, the market's true test these days is the reception accorded to individual bids and, in what little new business is being placed for automotive consumption, this procedure is being religiously followed. A Middle West buyer offered the other day to take on 1000 tons of malleable iron at $25 a ton. According to latest reports, he has not yet succeeded in securing an acceptance at that level, the producers asking $27, valley. It is quite likely, however, that a compromise offer on the prospective buyer's part of, say $26, would have proved acceptable. The situation with reference to pig iron must be considered apart from the outlook for steel. The former simply can not absorb the enhanced freight rates without showing a sharp bulge over pre-war levels. In the case of finished steel, this increment in costs is spread over a much higher ton price and the unavoidable bulge, expressed in per cent, therefore is more slight.

Pig Iron—What few round tonnage sales are consummated are negotiated at prices that remain undisclosed. The nominal market price, $27, valley, for malleable and No. 2 foundry, applies solely to carload transactions. Steel makers are reported to have sold some "off-grade" basic at $24, valley. The "off-grade" qualification is obviously for the purpose of not hurting the market.

Steel—Slightly improved movement of steel bars to automotive parts manufacturers is reported. Cold-finished bars could be had on fresh orders at as low as 3.25c., although the hot-rolled bar market is still at 2.10c., Pittsburgh, and producers of the cold-rolled figure on a differential of $25 per ton. Cold-rolled strip steel is quoted at around 6c. Reinstatement of parts orders by the Ford Motor Co. is expected to quicken shipping orders on old contracts. Sheet prices are working toward lower levels and 3.85c, for black has been spoken of for representative second quarter deliveries.

Copper—Although tonnages involved are light, a little copper is moving to the automotive brass foundries in the Middle West and Connecticut valley. While producers maintain 13c. as their price, so as not to injure the sale of the $40,000,000 bond issue rcently put on the market, sales in the "outside" market have been as low as 12½c.

Tin—Considerable Chinese tin is coming in, and this grade is more actively offered.

FINANCIAL NOTES

C. M. Hall Lamp Co. shows total assets of $1,539,988.27 in its annual report as of Dec. 31, compared with $1,561,007.83 the previous year. Current assets were $1,007,925.64 and current liabilities $29,994.75, against current assets of $1,037,213.52 and current liabilities of $254,375.26 in 1919. Net working capital was $977,930.89, compared with $782,838.26 the previous year. Fixed assets less depreciation reserve are appraised at $523,867.66. Surplus is $164,612.75 as against $211,251.76. No change was made in reserves for contingencies amounting to $345,380.81.

General Motors Corp. has sent a letter to common stockholders informing them that they will be given an opportunity to purchase sufficient fractional stock warrants to complete one full share of stock or to dispose of their present holdings of fractional stock warrants totaling less than one share in each case. The price paid will be the bid price for General Motors common stock as quoted at the close of business on the New York Stock Exchange the day previous to the one on which the order is received.

U. S. Radiator Corp., in its statement as of Jan. 31, reports the most successful year in the company's history, with gross earnings of $1,321,568.98, compared with $1,113,828 the previous year and $1,227,458 in 1918, the company's best previous year. Operating profits were $1,220,214.68 and total income less interest charges was $1,130,674.65. Net earnings were $927,059.51, after charges of $203,615.14 for depreciation on plant and equipment. This total was approximately $150,000 greater than in 1918.

White Motors Co. shows an operating profit after deducting all administrative expenses, but before providing for depreciation in inventories, amounting to $3,486,704. Reduction of inventories from cost to market values amounted to $1,193,927, leaving an operative profit of $2,292,776. The net profit available for dividends on the capital stock was $2,410,-014. This is equivalent to $4.82 a share. Gross sales for the year were $51,998,122 as compared with $41,667,696 in 1919.

General Aluminum & Brass Mfg. Co. reports for 1920 a surplus of $828,390.17 and net worth of $3,017,340.17. Manufacturing inventories were $1,118,583.66, current liabilities $526,723.80 and net current assets $1,166,-375.88. Plant account depreciation is given as $1,850,864.29, while $72,256.26 is due from employees on stock. Cash on hand is $22,-690.45 with accounts receivable $227,682.22.

American Bosch Magneto Corp. reports net profits for 1920 of $945,700, which is equal to $9.45 a share on the 100,000 shares of capital stock outstanding. In 1919 net profits were $921,963, equal to $9.21 a share, but in that year it was not forced to write off anything for inventory adjustment. Inventories at the close of 1920 were carried at $4,344,727, compared with $2,928,582 at the end of 1919.

Michigan Stamping Co. reports surplus of $316,974.71 with total assets of $4,352,881.49 as of Dec. 31. Total sales are given as $4,804,-142.56 and accounts receivable $664,195.84. Plant account is $1,963,752.94 and merchandise inventory $1,346,619.85. Reserves for depreciation are $290,916.77, and for Federal taxes for 1920 $70,000.

American-La France Fire Engine Co., Inc., and subsidiary companies, report net profits after Federal and Canadian taxes of $597,074, which after allowance for preferred and common stock dividends leaves a surplus of $252,308. With the previous surplus the company now has a total of $1,405,010.

Hood Rubber Co. reports sales for 1920 as $32,867,000, which compares with $25,444,016 in 1919. Tire sales were $8,700,000, against $6,500,000 in 1919. The balance sheet shows an increased surplus of over $1,000,000 after the stock dividend of $2,000,000 is deducted from surplus of Dec. 31, 1919.

Kalamazoo Chain Co. has been taken over by the Hodges Chain Co. of Galesburg, Mich., which has just been organized for $60,000, with $50,000 subscribed and $10,000 left in treasury stock.

Kroyer Motors Co. is offering the $500,000 unsold portion of an original offering of $1,500,000 7 per cent cumulative preferred stock at par ($100) plus a 100 per cent common stock bonus.

Clum Mfg. Co., Milwaukee, has increased its authorized capitalization from $100,000 to $250,000, to accommodate the growth of its business. Valentine Fina is president and general manager.

Autocar Co. has declared a dividend of 1½ per cent payable March 10. In the previous two quarters the company declared quarterly dividends of 2½ per cent.

Kelly-Springfield Tire Co. has declared a quarterly dividend of $1.50 a share on the 6 per cent preferred stock of the company, payable April 1.

Viking Motors Co., Detroit, with a capital of $100,000, has been incorporated to build aircraft motors and accessories.

Portage Rubber Co. stockholders have formed a committee to take care of the $1,500,000 refinancing program.

Pierce-Arrow Motor Car Co. has declared a quarterly dividend of $2 a share on preferred stock, payable April 1.

Watson Products Seeks Funds to Continue Plant

SYRACUSE, N. Y., Feb. 28—Attorneys for Milton Delano, receiver for the Watson Products Corp., have obtained an order to show cause why he should not be authorized to issue $250,-000 worth of receivers certificates in order to continue the business of the company under a schedule prepared by Albert A. Kessler, president of the company, who has been conducting the factory for the receiver. The schedule filed with the court by Kessler shows quick asests of $913,057 including $74,554 in cash and the remainder in inventories. The statement shows that a reduction of one-third from stock prices has been made from the current value of the inventory.

The receivership is a friendly one to permit reorganization of the Watson Products Co. as the Watson Truck Corp. The old company owns 2001 shares of the common stock of the truck corporation. The only assets of the new company consist of the preferred stock of the Dunkirk Axle Corp. which is a reorganization of the Empire Axle Co.

Kessler states that an option already has been given for the sale of this entire block of preferred stock in the axle company and that "if the assets of the Watson Products Corp. should be merged with the assets of the Watson Truck Corp. and a sale should be made under the option, it would create a large amount of working capital for any company succeeding to its business."

Bank Credits

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, Mar. 3—The money market last week was quiet with a small supply and with light transactions. Call money ruled at 7 per cent with a range of 6 per cent to 7 per cent, the same as the previous week. Time money was unchanged at 6½ per cent to 7 per cent for 60 and 90 day paper and 6½ to 6¾ per cent for the longer maturities.

The week-end statement of the New York Federal Reserve Bank showed a less favorable reserve position. Gold reserves declined $12,512,000, and total cash reserves $13,873,000. Total bills on hand increased $24,452,000 and total earning assets $24,752,000. Federal Reserve Notes in circulation in this district increased $4,392,000, while Federal Reserve Bank Notes decreased $680,000.

For the first time in the current year the reserve ratio of the Federal Reserve Bank as a whole declined. The ratio of gold reserves to Federal Reserve notes in circulation after setting aside 35 per cent against net deposits declined from 58.5 per cent to 58.1 per cent. Gold reserves increased $7,663,000. Federal Reserve notes in circulation increased for the first time this year by $14,262,-000. Federal Reserve Bank notes declined $4,106,000. Total bills on hand increased $35,475,000 and total earning assets $35,227,000. Net deposits increased $26,479,000 and bills discounted secured by Government war obligations increased $13,793,000.

The London money market appears to be in about the same strained condition that the New York market was in December. Short term discounts touched 7¼ per cent, the highest since the November panic of 1890. The official discount rate of the Bank of England, which is ordinarily "on top" of the market, is only 7 per cent. Partly responsible for this money tightness, undoubtedly, is the pressure of income and excess profits taxes which are due by March 31, the end of the fiscal year.

AJAX PASSES DIVIDEND

NEW YORK, Feb. 28—Directors of the Ajax Rubber Co. have decided to pass the quarterly dividend of 1 per cent on the common stock. The dividend was reduced three months ago from $1.50 a share to $1. The action of the directors was influenced by the poor showing made last year. They felt that all the company's resources should be reserved to finance business to meet the demand for tires which it is expected will increase with the approach of spring. They were informed that reports from dealers indicate an earlier resumption of normal operations than had been expected.

Stockholders of the company re-elected the retiring directors with the exception of Harold W. Stimpson, who declined to serve another term. Benjamin Briscoe was elected to the board in his place.

Men of the Industry

G. S. Crane, who has been manager of the Cleveland office of the Cutler-Hammer Mfg. Co., will become manager of controller sales at the main office in Milwaukee. L. B. Timmerman will be in charge of the Cleveland office, and will act in the capacity of assistant to A. G. Pierce, manager of the central district. The Cincinnati office will become a part of the central district with R. I. Maujer as branch manager. E. N. Lightfoot will assume the title of manager of the heating department with headquarters at the New York works.

J. G. Utz, who was associated with Christian Girl in the Perfection Spring Co. and Standard Parts Co. for about ten years, and who, since he resigned from Standard Parts, February last, has devoted a part of his time to the consulting work of the C. G. Spring Co. and the balance of his time to expert spring consulting for automobile manufacturers, has arranged to give up his consulting office and devote all of his time to the C. G. Spring Co. as vice-president.

George C. McMullen, who has represented both the Timken Roller Bearing Co. and the Timken-Detroit Axle Co. in the Pacific Coast territory for the last three years, will in the future devote his entire time to sales engineering in the sole interests of the Timken Roller Bearing Co. He will maintain his offices in Room 450, Monadnock Bldg., San Francisco. McMullen's former assistant, C. H. Brooks, will take care of the business of the Timken-Detroit Axle Co.

J. F. Richman, one of the old guard of the automobile business, has resigned as superintendent and production manager of the Allen Motor Co. of Columbus. Richman has not disclosed his plans for the future, but it is understood that a private enterprise in Columbus will occupy part of his time. Richman has been identified with the automobile industry since the early days of the Olds Motor Works at Lansing, Mich.

E. C. Shaw, director and for many years vice-president of the B. F. Goodrich Co., has been named one of three members of the new state board of administration of Ohio by Governor Harry L. Davis. Shaw has accepted the appointment, but will continue his official identification with Goodrich as a director, in connection with his new duties.

W. W. Clark, export manager of the Hart-Parr Co., has just returned from a four months' business trip through Europe. He found Europe suffering from the same economical troubles as America, but with conditions much worse on account of the unstable exchange which has made trade almost prohibitive.

Frederick P. Nehrbas, connected with the Premier Motor Corp., has resigned, effective March 1. After a short rest, it is his intention to locate along the Great Lakes or in the New England States, where he was intimately known prior to locating in Indianapolis.

C. B. Rose, for the last few months supervisor of the Moline Engine Co. plant, has been appointed general manager and will be formally elected vice-president of the company. Rose will continue his connection with the Moline Plow Co. as consulting engineer.

E. Gruenewald, who has been associated with the R. & V. plants since 1906, is entering the field as consulting engineer, and will continue affiliations with the R. & V. organizations as consulting engineer for both the Moline Engine and the R. & V. Motor.

John S. Ogilvie has resigned as assistant treasurer of the Mutual Tire & Rubber Co. and as treasurer of some of its associated corporations and is now secretary-treasurer of Horn, Severson & Ogilvie, Inc., general insurance brokers, New York.

Homer M. Eichelberger, for the past three years associated with the advertising department of the Franklin Automobile Co.; Syracuse, in charge of production, has resigned, to become advertising manager of the Syracuse Washing Machine Corp.

Albert E. Rosenberg has resigned as vice-president and purchasing agent of the E. G. Mfg. Co. to become a representative for Claussen Tube Works, Hardy Mfg. Co., U. S. Metal Goods Co., Waldenburg Bros. and American Auto Lamp Co.

C. E. Franks has been appointed export manager of S. F. Bowser & Co., Inc., in all export markets outside of Europe. Ralph G. Schulze, former export manager, has been made European managing director.

Harry P. Meredith, former manager of manufacturing of the Curtiss Aeroplane & Motor Co., Buffalo, has been made general works engineer of the Maxwell-Chalmers Motor Co., Detroit.

Frank K. Dolbeer, one of the old timers of the Willys-Overland organization, has resigned as treasurer. The duties of the office will be taken over for the present by J. H. Gherkins.

J. M. Crawford, chief engineer at the Allen Motor Co., has been promoted to manufacturing manager, but will retain charge over all engineering departments.

Mitchell Mackie, sales manager of the Waukesha Motor Co., Waukesha, Mich., has resigned, effective March 1. His plans for the future are not announced.

Robert Rubin has been added to the engineering staff of the Radcliffe Turbine Drive Co., New York, makers of the new turbine drive for motor cars.

Guy C. Core, former advertising manager of the Jackson Motors Corp., Jackson, Mich., has joined the Horsting Co. advertising bureau, Chicago.

W. H. Ellis and C. B. Clarke have been added to the sales force of the Hilo Varnish Corp., Brooklyn.

J. Wesley Bean, formerly secretary-treasurer of the Acme Universal Joint Co., Kalamazoo, has been appointed auditor of the city of Kalamazoo.

C. F. Nelson, of Minneapolis, has accepted the general superintendency of the plant of the Reed Foundry & Machine Co.

C. A. Woodruff, former purchasing agent for the Chalmers Motor Co., the Saxon Motor Car Co. and the Liberty Motor Car Co., has joined Briscoe Motors as director of purchases.

SCHARTOW FORMS NEW COMPANY

MILWAUKEE, Feb. 28—F. E. Schartow, founder and president of the Schartow Mfg. Co., which moved from Racine, to South Milwaukee about a year ago, has disposed of his interests and has organized the Schartow Iron Products Co., which will locate a plant in Racine. It will manufacture a diversified line of automotive equipment, hardware, etc. Work is under way on a foundry and machine shop to be ready about March 21.

The Schartow Mfg. Co. of South Milwaukee, following the retirement of Schartow, has changed its corporate style to the Midland Co. The product, including chains, hardware, harness and saddlery hardware, etc., will continue to be trade-marked "Sharto." The present officers are: President, R. A. Nourse; vice-president, T. E. Ward; secretary and treasurer, C. P. Nourse.

W. M. Anthony Retires as Maxwell Treasurer

DETROIT, March 1—W. M. Anthony, treasurer of the Maxwell-Chalmers organization, has resigned to take effect today. No successor has been appointed, but it is understood Walter P. Chrysler, chairman of the management committee, has selected a man for the post. Anthony, who is 70 years old, has been with Maxwell-Chalmers a long time and his retirement, according to officials, is due to advanced age. It became known today that a general reorganization of the Maxwell-Chalmers personnel is being carried out with the idea that the company's position would be bettered by the induction of new officials into several positions.

The reorganization plan started with the resignation of Roy M. Hood, long-time purchasing agent, who was succeeded by A. C. Downey. The resignation of Ordon Muir, advertising manager, who was succeeded by W. J. Mattimore, and the acquisition of A. E. Barker as sales manager were in accordance with the determination of officials to rejuvenate the organization. An official of the company said many department heads had formed friendships and alliances which precluded giving their best efforts to the organization.

President Ledyard Mitchell said today that the company, at the time of the shutdown last July, had 16,000 Maxwell cars on hand and 5500 Chalmers, of which 10,000 Maxwell and 4000 Chalmers have been sold. President Mitchell said the company is turning out 50 Maxwells and 20 Chalmers daily.

Stearns Earnings Show 10 Per Cent Increase

CLEVELAND, Feb. 28—Profits of the F. B. Stearns Co. for 1920 exceeded those of 1919 by about 10 per cent, stockholders were informed at the annual meeting. Business for January was as good as in the same month of 1920 and the company now is operating at about 95 per cent of normal. The parts business has been entirely satisfactory and the company now makes every part that goes into the Stearns car.

Richard Garlick, treasurer of the Youngstown Sheet & Tube Co., was elected a director to succeed Paul Wick of Youngstown who resigned. The other directors were re-elected.

Calendar

SHOWS

Mar. 5-12—Atlanta, Annual Automobile Show, Atlanta Automobile Dealers' Ass'n, Auditorium, Virgil Shepard, Mgr.

Mar. 5-12—Brooklyn, Annual Automobile Show, Brooklyn Motor Vehicle Dealers' Ass'n, 23d Regiment Armory, George C. Lewis, chairman.

Mar. 5-12—Pittsburgh, Annual Automobile Show, Automotive Ass'n, Inc., Motor Square Garden, J. J. Bell, Mgr.

Mar. 5-12—Atlantic City, Annual Automobile Show, Automobile Trade Association of Atlantic City, Million Dollar Pier, A. H. Generatsky, Mgr.

Mar. 7-12—Syracuse, N. Y., Annual Automobile Show, Syracuse Automobile Dealers Ass'n, Armory, Howard H. Smith, Mgr.

Mar. 7-12—Indianapolis, Annual Automobile Show, Indianapolis Automotive Trade Ass'n, Automobile Bldg., State Fair Grounds, John Orman, Mgr.

Mar. 7-12—Nashville, Annual Automobile Show, Nashville Automobile Trade Ass'n, Page Bldg.

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

Mar. 14-19—Washington, Annual Automobile Show, Washington Automobile Dealers' Ass'n, Rudolph Jose, Chmn.

Mar. 19-26—Detroit, Annual Automobile Show, Detroit Automobile Dealers' Ass'n, Morgan-Wright Building.

April 3-9—Denver, Annual Automobile Show, Auditorium.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

April—Chattanooga, Tenn., Spring Automobile Show, Chattanooga Automotive Trade Ass'n, Sunday Tabernacle, C. A. Noone, sec'y.

FOREIGN SHOWS

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections.

April, 1921—Sofia, Bulgaria, Tractor Trials, under the Bulgarian Ministry of Agriculture.

May 28, 1921—Czecho-Slovak International Automobile Exposition of Cars, Trucks, Tractors, Motorcycles and Equipment. Prague.

May 28-June 8—International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

CONVENTIONS

May 4-7—Cleveland, National Foreign Trade Council.

May 17-19—Buffalo, Convention of Factory Service Managers, Auspices of Service Committee, N. A. C. C.

Oct. 12-14, 1921—Chicago Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

RACES

July 24—Grand Prix, Le Mans.

S. A. E. MEETINGS

Boston section—March 18.

Buffalo section—April 19—Paper on "Carbureter Performance," by F. C. Mock.

Dayton section—May 3.

Detroit section—March 25—Discussion of "The Relation Between the Industry and the Department of Engineering Research of the University of Michigan," by Prof. E. A. White.

Metropolitan section—March 10—Paper on "Brakes," by H. G. Farwell.

Metropolitan section—April 14—Paper on "Low Grade Fuel Carburetion," by A. H. Beach.

Midwest section—March 11—Discussion of storage batteries.

Minneapolis section—April 6—Discussion of repair equipment.

Washington section—March 18—Highway and Highway Transport Trading.

Washington section—April 1—Aeronautical Engineering Session.

Boston S.A.E. Section Visits Rolls-Royce Plant

SPRINGFIELD, MASS., Feb. 25—Over 125 members of the Boston section of the Society of Automotive Engineers and guests met here today for the regular monthly section meeting, which took the form of a visit during the afternoon to the Rolls-Royce factory where several hours were spent, and an evening meeting starting with a dinner and followed by an address on a Comparison of European and American Automotive Practice by Maurice Olley of the Rolls-Royce company. Both the visit and the evening meeting were most successful, many members and guests attending from Boston, Hartford, Syracuse, and other New England cities. President David Beecroft attended.

During the factory visit the party was divided into groups of ten who under a leader were taken through all factory departments and stops made at nearly every stage of manufacture. Every effort was made to let all get any information desired. Factory departments were literally unlocked for the occasion.

At the evening meeting Mr. Olley gave one of the best comparisons of the motor industry in England, France and America that has been heard. The present British design has been largely determined by such factors as cost, competition by motorcycles, roads, climate, limited size of the industry, the spirit of adventure in the Englishman and lack of definite money standards.

The French car has been largely determined by the demand for high speed on the long straight roads, adequate brakes, carburetion intended specially for speed, stiff springs, and without any special claims to quietness. It is uncomfortable to ride in and uncomfortable to operate.

The American car is the most convenient vehicle in the world to operate and to drive and is best able to get any place whether there is a road or not. It is not a speed monster as are the European cars; it is not pleasant to steer; its brakes are deplorable; and its bodies are not comfortable or well made.

Service Men to Hold Convention in Buffalo

NEW YORK, Feb. 25—Plans are rapidly being completed for the semi-annual convention of factory service managers under the auspices of the Service Committee of the National Automobile Chamber of Commerce. It has been definitely decided to hold this next convention in Buffalo and the dates will be May 17, 18 and 19. Among the subjects under consideration for discussion are:

Advantages and disadvantages of the unit replacement system for continuous service.

Service equipment.

Service department organization.

Growth and responsibilities of the service department.

Field organization.

Relation between the engineer and the service department.

Better co-operation between equipment service stations and dealer service stations for the benefit of the owner.

MOLINE ENGINE RESUMES WORK

EAST MOLINE, ILL., March 1—The Moline Engine Co., after two months of idleness, reopened to-day with a force of 60 men. It will be gradually increased, company officials announce. The company produces the poppet valve engine for the R. & V. Knight automobile.

DePalma in Ballot First at Los Angeles

LOS ANGELES, Feb. 28—Driving 50 miles at an average speed of 107.3 miles per hour, Ralph DePalma in a Ballot, on Beverly Hills Speedway, won the opening event of the new championship season this afternoon with Milton, second; Sarles, third, and Murphy, fourth. DePalma established a new 50 mile record for 183 cu. in. cars. Preceding the final race were four sprint matches of 25 miles each. DePalma won the first from a field of nine starters averaging 106 miles per hour; his last lap was better than 111 miles per hour, the fastest the track ever was driven.

Sarles won the second heat averaging 107 miles per hour. Murphy won the third heat averaging 102 miles per hour. Milton won the fourth averaging 104 miles an hour. Winners did not start in succeeding heats. The time was the fastest and the driving the best ever seen here. It was DePalma against the field, all but one of the other drivers using Duesenberg motored cars. The exception was Sarles in a Monroe.

TRUCKS CLEAR MARYLAND ROADS

BALTIMORE, Feb. 25—Maryland's motor fleet of twenty-five trucks equipped with snow plows, opened up every mile of road in the state, after the blizzard of Feb. 21. In the western part of the state the plows had to go through snow fifteen inches deep. The big trucks were kept on a 24-hour shift, chauffeurs working in two shifts. Farmers, dairymen and freight trucking firms that carry on inter-city business were delighted with the work of the new snow fighters.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV NEW YORK—THURSDAY, MARCH 10, 1921 No. 10

How Can Automotive Production Costs Be Lowered?

This is not the complete answer, but it is one answer by a man who has studied production in most of the large shops of the industry. Interesting discussion of progressive and departmental manufacture.

By George M. Meyncke*

MANY economists, after a profound study of the recent stagnation period, have agreed on a verdict. It is that overproduction is practically impossible—it is merely underconsumption that we suffer from. The Public, they explain, are merely depriving themselves of their wants because of the delays they suffered and the prices they paid in addition to the suffering.

It is true that the Public has been plunged from a feverish urge to stop purchasing because there was not enough goods to go around, to the frigid plea of "Buy Now" campaigns.

It is scant wonder that there is indecision in the minds of the automobile builders as to which is the dream and which the reality, and no doubt we will continue to swing pendulum-like back and forth between the two extremes unless all phases of the automobile industry bend their efforts toward stopping the pendulum somewhere near its perpendicular position.

A local distributor has informed me that several of my neighbors want to buy a car and will do so "when prices come down." These neighbors are obeying to the letter of the law the now extinct solicitation to stop purchasing and they refuse to be excited by the "Buy Now" appeal.

*With the Oesterlein Machine Co.

This is but a concrete example of a problem that is staring all manufacturers in the face. That is, the problem of producing and marketing their products at a price which can be paid by those who are anxious to obtain their products.

Production Costs

On the surface it would seem that the limit has about been reached in the automobile industry from the production end. The industry includes the world's greatest producers. What production problems are left to be solved? How can production costs be lowered?

This can be answered generally in one sentence.

> **The automobile manufacturer is behind the times from the shop equipment standpoint and is not in a position to avail himself of the best the machinery market offers.**

This extreme statement is probably contrary to the common understanding and calls for explanation.

The machine tool industry has confronted and is ready to emerge from an unusual position. Unlike the automobile, its production was encouraged instead of curtailed during the war and thousands of new tools were built and put into service. A machine tool stays in service many years. Tools in use that are thirty years old are not uncommon.

Generally speaking, the same tools built during the war are in use to-day in automobile shops.

However, during and after the war, the machine tool builders have attacked the problem of reselling their old market by the introduction of more productive tools. A concrete example may make this point clear.

There were approximately 2,250,000 passenger cars built in 1920 and in them approximately 11,000,000 connecting rods were used. If these 11,000,000 connecting rods were all made in one shop, a certain one of the essential machining operations would require 132 of the best of machines (on a 2000 working-hour-year basis) made prior to the war, whereas it would be possible to machine them on 45 of the modern machines available to-day.

By actual count in ten large shops and the proportioning of their production to the total yearly production, there were, instead of the theoretical 132 "old style" machines, a total of 786 machines used to get out the 1920 production of this operation or almost six times the number necessary for the theoretical centralized connecting rod shop.

To rework the field for that particular operation on connecting rods, the old machines can be replaced by the new at the ratio of about three to one.

Incidentally, this could be the foundation of argument for the parts manufacturer with very fine specialization of products such as a connecting rod company, with an ambition to supply the entire industry.

When the production ability of some of these new tools is studied, the real scope of their cost lowering value is apparent. They are not confined to any one class of work as is evident from the following.

There is a grinder capable of grinding operations on small hardened parts at the rate of over one million parts per year. There is a milling machine capable of milling parts, such as yokes, at the rate of one million per year. There are drilling machines capable of drilling fairly large holes at the rate of half a million holes per spindle per year.

Specialized Machine Tools

Such machine tools are commonly classified as "specialized tools." There is a fine hair distinction between them and the so-called "special machines" in that the former are the developed product of machine tool builders and the latter are odd machines built for a single fixed purpose.

The general plan followed in specialized machine tools has not been to build the older machines in duplex or triplex and thus multiply the output per machine, but to employ but a single cutting or abrasive tool and make it capable of greater output, or in other words, to design around the actual ability of a single stock removing medium at more or less of a sacrifice of the versatility of the old machines of general application.

When this idea is successfully carried out production increase is obtained with a corresponding decrease in maintenance.

The automobile manufacturers have stimulated and even assisted in the development of much of this new order of production machinery and where they have not actually assisted the automobile manufacturer has furnished the market for the manufacturer who developed his tools unaided.

Some new shops have fortunately been in a position to start with much of this new equipment. As a whole, however, the manufacturers have not seized the opportunity of lower production costs which these new tools make possible. There are both actual and fancied disadvantages that operate against the installation of such machinery.

The automobile industry is much more responsive to improvements than others. They have witnessed such rapid development in their own product that they even anticipate it in other industries. Recently the idea has grown that the curve of progress has reached its peak and will hold a flat for some time. Whether this is true of the automobile itself or not, the writer is not in a position to say. On the question of production machinery, he believes that the high point is yet to come. Witness the new production machinery that has been announced since the war and which is augmented almost weekly as new ideas are perfected.

There are frequently fixed ideas in the minds of production engineers as to the ultimate possibilities in production and these ideas are set too near the limits of past practice.

Progressive Manufacture

Perhaps the greatest actual handicap to new machinery is the almost universal use of progressive manufacture. The mere idea that progressive manufacture shows symptoms of inadequacy is received with consternation by its advocates.

Progressive manufacture, from the machining standpoint, consists of the grouping of all machines required to make, say a universal joint, in a universal joint department, in charge of a foreman responsible for each machining operation necessary to complete the joint.

When one or more machines are required for milling or drilling as many joints per day as the schedule requires, this system is excellent. Suppose, for example, that the schedule calls for production at the rate of 200 universal joints per day and one milling machine and one drill are capable of that output. Each operator is kept busy at his particular machine and there is no accumulation of parts. Now suppose this equipment is replaced with a milling machine capable of producing at the rate of 140 universal joints per hour or 1120 per day.

This means that in less than two hours the output of the department is completed as far as that operation is concerned. The more capable machine is idle three-fourths of the time and a possible saving of production costs is not obtained.

Another job, say the steering knuckle, could be run on these machines when the universal joint output is completed. But this is impractical, because steering knuckles are made in the steering knuckle department under a steering knuckle foreman, who is indifferent to the worries of the universal joint foreman.

Departmental Manufacture

Progressive manufacture displaced departmental manufacture. With this system all chucking lathe work was done in the chucking department under a chucking lathe foreman, and all drilling in the drill department under a drill department foreman.

There are some classes of work, such as automatic screw machine, and frequently grinding, that, because of the skill and close supervision required, have always been handled departmentally.

In reality the introduction of specialized machinery is merely putting other machining operations at par with such classes of work that have previously been inapplicable to progressive manufacture.

To realize on the lower production costs offered by such machinery progressive and departmental manufacture is subject to review and revision from a cost per piece basis.

Foremen will never agree to combine. There is a fear of self-elimination. During the recent rush for production, such a change in system was impossible. To-day it is a cost reducing problem for the management as a whole.

Production Department Investments

Production engineers are not hired primarily to search for investments. In defense let it be said that they are not supervised from the "interest on our money" basis. They think and talk output limits and are ever increasing schedule from the equipment at their command.

In figuring a possible savings on equipment, their minds run in the single channel of saving operators' wages. They do not count the cost of supervision, floor space, upkeep, power, belts or motors and the endless little things that the auditors know as items of overhead that indirectly affect the cost of the finished product.

In considering the replacement of present equipment with more modern equipment, it may result in worthy gains for the auditor to sit in with the equipment committee having an eye for the production department investments so often discussed at such committees.

Unless the producer of comparatively small quantity can utilize more productive equipment, the gap between his costs and the large quantity producers will widen, a fact that reacts against his reaching the desired quantity goal.

Some shops maintain what are called "Flying Squadrons." These consist of capable men who are plugged in at whichever department lags behind the schedule and requires their assistance. Instead of continuing with slow equipment, the small shop can enlarge upon the "flying squadron" idea and progress their men to the equipment on which they can produce to greater advantage.

There is also a tendency to keep one machine constantly on a certain job. There is a point at which the potential possibilities of production become so great that changing from job to job on a single machine results in a lower cost per piece.

Making use of more productive machinery in the low quantity shop is more of a problem of tool and fixture design and of the training of operators than in the high quantity shop.

The grouping of similar parts and standardizing on fixtures makes possible the utilization of high production machinery, but also necessitates the training of more men to change equipment and to set up machines.

There is opportunity for the combined efforts of the engineering and production departments in a study of parts from the standpoint of material and processes of manufacture. Parts from sheet metal, for example, can now be made cheaper in some cases if castings or forgings are used in connection with the latest developments in machining methods. The relation between the number of operators and the cost of machining differs as improvements in handling operators are developed.

Standardization Work in Belgium

THE Association Belge de Standardisation was formed in April, 1919, in order to study the question of standardization from the commercial and technical points of view in all branches of industry. It consists of important technical and industrial associations in Belgium. A general committee has been chosen to direct the activities of the association, to examine any proposals presented and to keep in touch with similar organizations in foreign countries, in order that the members of the association may profit from results obtained elsewhere, or may, if required, assist in the establishment of international standardization. In each case where the committee decides to attempt standardization, it will appoint a "Technical Committee" of experts, who will report and if necessary consult individual producers and consumers.

Five Models Included in New Line of G. M. C. Trucks

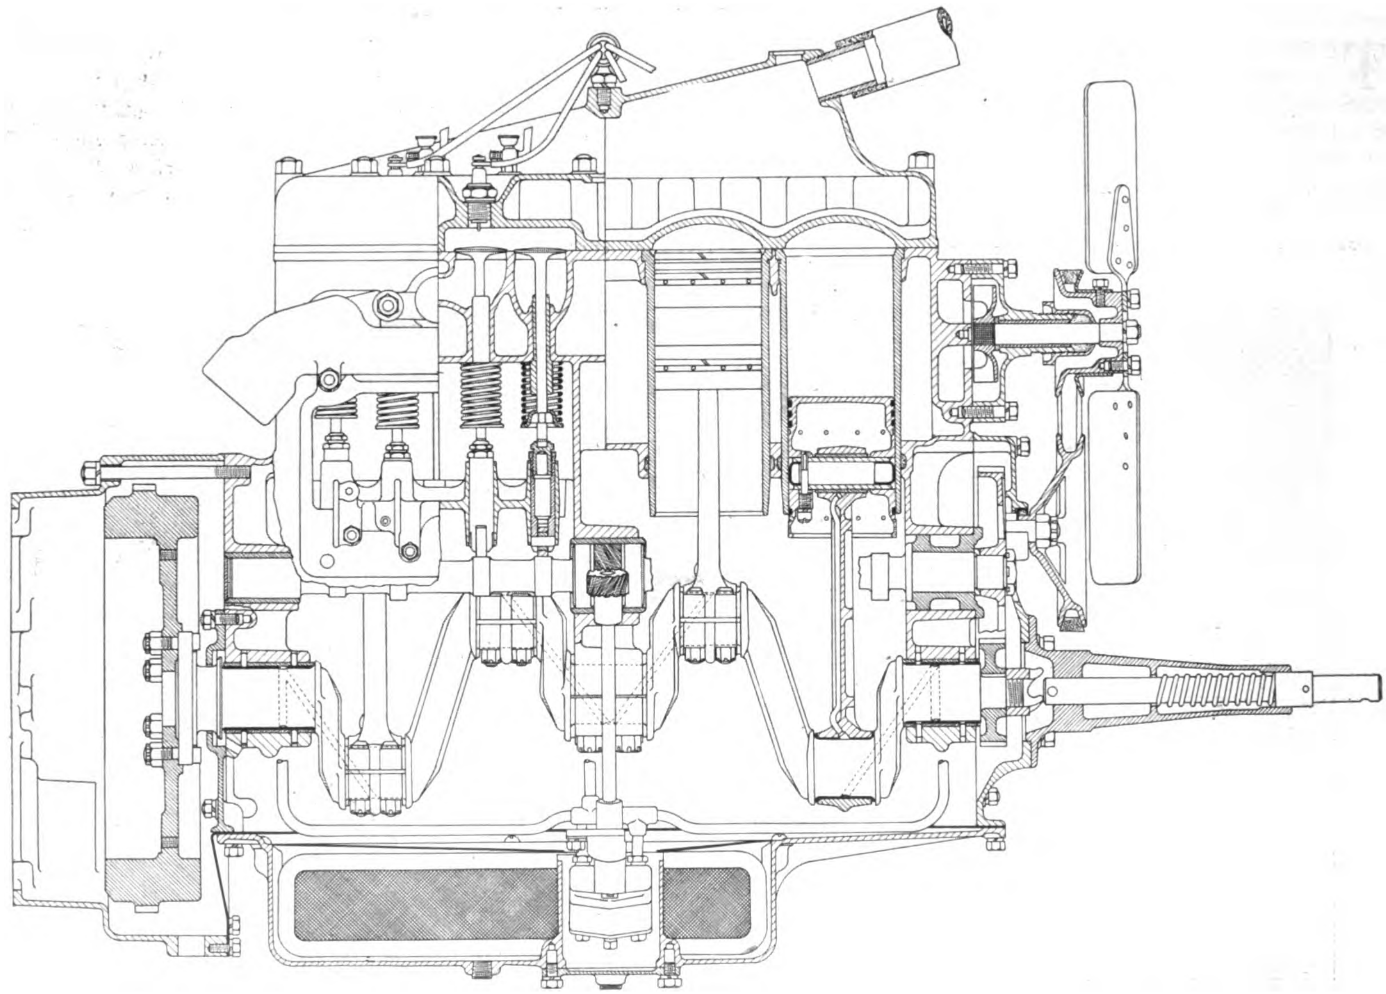
Three larger sizes are equipped with seven-speed transmission, having two sets of constant mesh gears. Will manufacture own engine in three sizes, all of similar design, and all equipped with removable sleeves. New trucks will be faster and more powerful than former models.

By J. Edward Schipper

THE General Motors Truck Co. is just beginning production on a new line of trucks which represents a development of the line previously marketed. The new line is made up of five models. Three engines, all of similar design and all products of the new General Motors truck engine plant located in Detroit, are used in these trucks, the smallest engine being used in both the ¾ and 1-ton, the largest in both the 3½ and 5-ton sizes, and the intermediate size in the 2-ton only.

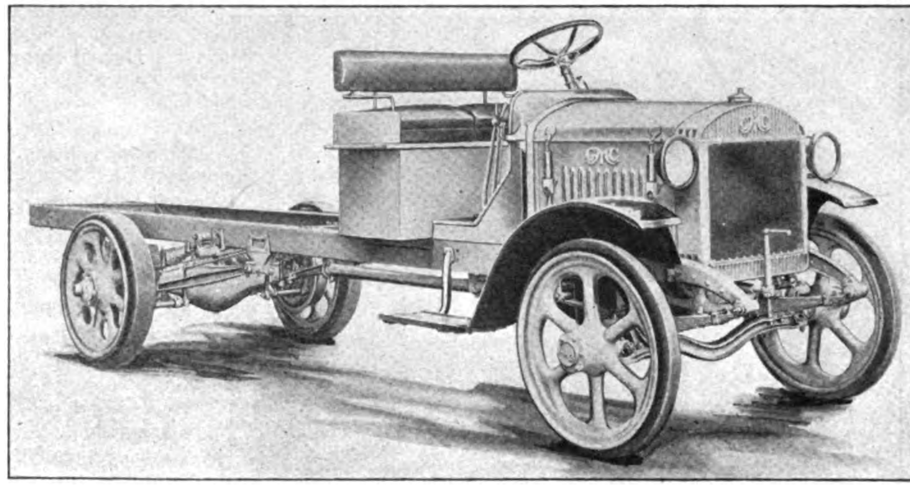
The trucks are designed with an idea of furnishing uninterrupted transportation and incorporate a great many features of interest from the maintenance side. The new engine may be said to have been designed with a view to keeping maintenance cost as low as possible and reducing to a minimum the period of tie-up when repairs become necessary. As compared with the old line of G. M. C. trucks, the new line is faster and more powerful. Heretofore, the design has been laid out with the principal idea of supplying sufficient power for all circumstances. However, with present road and transportation conditions the factor of speed is as important as that of power.

By improvements in the design of the engine, considerably more power, or rather more torque, has been se-



Longitudinal section of G. M. C. engine. Note removable sleeves, large water spaces and arrangement of water pump on fan spindle

cured, although the cubic displacement remains about the same as in the older model engines. The engines run at higher speeds, and this, in connection with a specially designed gearbox, with an additional countershaft reduction, provides twice the number of available gear ratios and, consequently, widens the range of performance and gives a flexibility to the vehicle not approached in the old models.



Two-ton model K truck chassis of G. M. C. line

The new G. M. C. engine incorporates some features more or less novel in truck engine design. These include removable cylinder sleeves, force feed lubrication, superheated high velocity intake manifold, interchangeability of all wearing parts, removable cylinder heads, removable motor support arms, connecting rod bearings cast integral with the connecting rods, combination thermo-siphon and pump cooling system, removable valve assembly and non-scoring piston pins.

Probably the most interesting feature of the engine is the removable cylinder sleeve. These sleeves are gray iron castings, machined to very close limits both inside and out. In manufacture, they are first cut off, then rough-machined all over on the outside and inside. After a period of aging, the bore and the outside are finished. The advantages claimed for this construction are interchangeability, ease of replacement and elimination of misalignment of the cylinders because of shifting of cores in casting. Should a cylinder wall be scored through lack of lubrication or any other cause so as to necessitate replacement, it is possible to make a replacement in 4 hours—a great saving in time as compared with the 10 days to 2 weeks usually required for regrinding. Not only does this result in a saving in service cost, but also in a reduction in the lay-up time of the truck.

The cylinder liner being of uniform wall thickness, expansion of the liner will be uniform, thus obviating compression leaks due to irregular expansion. The sleeve comes in direct contact with the water, and the

water capacity of the jacket has been greatly increased. The sleeves are longer than the total length and throw of the piston, and the exterior of the sleeve is machined to extremely close limits to afford a good seat for the gasket. The top gasket is of asbestos, and is placed immediately under the flange of the sleeve, while the lower gasket is of compressed cork and is placed in a recess in the cylinder casting. The cork gasket is compressed when the sleeve is inserted, the lower end of the sleeve being slightly tapered. Since the sleeve is a press fit, a perfectly water tight joint between sleeve and cylinder block is obtained. After the sleeve is inserted and sealed, it is held in place rigidly by the cylinder head, which is bolted down with twenty-four ⅝-in. studs. When the sleeves require replacement they are withdrawn from the cylinder casting by the use of a special tool which resembles a wheel puller.

The separate cylinder head casting is of semi-steel and is readily removable for access to the combustion chamber, valves and piston heads. The heads are made large so as to provide a large body of water over the valves and combustion chamber.

The cylinder block and crankcase are cast in units of semi-steel, and no wearing parts which are not replaceable are secured to any part of the block with the single exception of the valve seats. These are provided with a sufficient amount of metal to allow of reseating the valves many times more than required during the normal life of the engine.

The engine has three-point support, ball and socket mountings being employed at the two rear supports. The frame on which it is carried is of the semi-flexible type. The ball and socket joint is held together by a bolt which passes through the joint and extends below the engine hanger far enough to enable the insertion of the heavy coil spring. In addition to giving a three-point flexible suspension, the supports will yield in the event of excessive distortion of the frame. Any wear that takes place in the joint is compensated, as the spring provides an automatic takeup. The front support of the engine is in the form of a collar on the starting crank housing, which is bolted to the timing gear cover. This suspension point is also protected by the spring and clamp method to allow for disalignment.

There are four piston rings, three above the piston pin and one in the skirt below the pin. Grooves are cut in the piston face immediately below each of the two lower rings. Holes are drilled from the bottom of these grooves to the interior of the piston, providing a return passage for surplus oil. The rings are of the plain, diagonally split type, except the second ring from the bottom, which is an expansion ring with an overlapping joint and is so designed that the pressure between the two pieces keeps the ring tight in the groove and also against the wall.

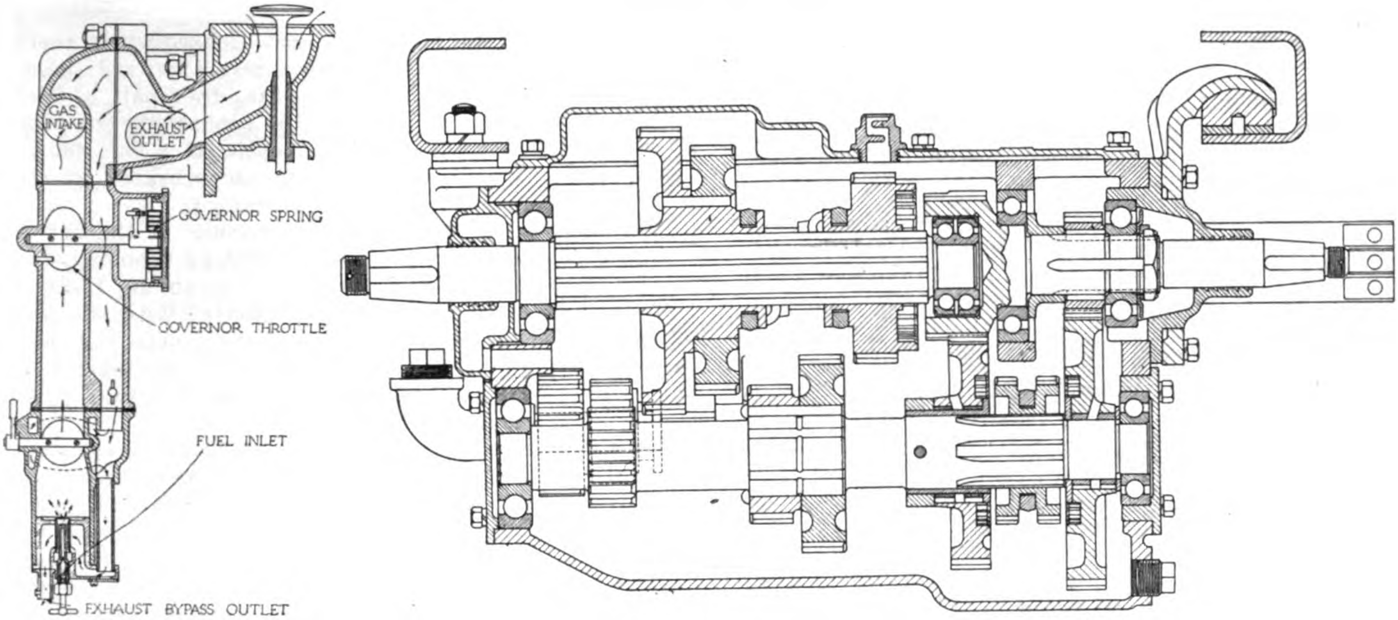
The non-scoring feature of the piston pin is due to bronze plugs inserted in the ends of each pin. This metal is exceptionally soft bronze, so that in the event of the pin working its way into contact with the cylinder wall it will not score it.

The connecting rods are drop forgings of high carbon steel, the upper end being bored and reamed and provided with a bronze bushing forming the bearing on the piston pin. The lower end of the rod and the cap are electro-plated with copper after being machined. They are then tin plated, after which the bearing metal is cast into the head. This method of construction is used because of the impossibility of securing a good contact between the bearing metal and the steel rods by other means. As a service feature, this method of babbitting the rod has been found advantageous in passenger car practice and should work out well for trucks also. Instead of rebabbitting a rod, the entire rod is replaced and the used rod returned to the factory. Rods can be readily changed by dropping the pan. For long distance transportation, it would be feasible to carry a replacement rod along in the tool box.

Provision for Starters on All Models

The crankshaft is a high carbon steel drop forging, supported by three bearings held by webs in the crankcase. The center bearing is provided with flanges to take the end thrust. The flywheel is semi-steel, machined all over and balanced, and is fastened to the flange of the crankshaft by six alloy steel bolts. Starter teeth are cut on the flywheels of all engines, and electric starting can be provided on all models.

The camshaft is drop forged of high carbon steel, the cams being forged integral with the shaft. Both the bearings and cams are hardened and ground to size. The



At left, sectional view of exhaust heated inlet manifold and carbureter. At right, longitudinal section of transmission which has two speed ranges, giving 7 forward and 2 reverse speeds. This is made possible by use of two constant mesh gears with positive clutch between them

camshaft is driven by helical gears and the oil pump is driven off the center of the camshaft by a helical gear and vertical shaft. The engine is oiled by a full force feed system. The oil pump, which is located in the bottom half of the crankcase, forces the oil to the three main bearings and to the three camshaft bearings. From the camshaft bearings it is returned to the crankcase. From the three main bearings it passes through conduits drilled in the webs of the crankshaft to the four connecting rod bearings. From the four connecting rod bearings it is forced through copper conduits secured in the side of the connecting rods to the piston pin bearings, from which it returns to the sediment chamber.

Lubrication Details

Pressure is regulated by a ball and spring by-pass valve. The capacity of the pump is such that there is a surplus of oil at all times. This surplus passes through the by-pass valve and is discharged directly on the timing gears. The oil which is forced out of the ends of the main bearings and connecting rod bearings is thrown out as spray and lubricates the cylinder walls and valve lifter assemblies. The oil pump is hung in the crankcase on a bracket to which it is securely fastened. It is of the gear type and is driven from the camshaft through a splined vertical shaft. The oil pan, which is an aluminum casting, incorporates sediment chambers through which the oil must pass before it returns to the pump intake. The first settling chamber is under and around the pump, although it is separate from the intake. The major portion of the dirt or sediment contained in the oil is deposited in this chamber before the oil passes to the last settling chamber, and it is possible to readily drain this by the removal of a plug beneath the pump. The first settling chamber has a capacity of about 1 pt., which is all the oil that is lost in cleaning the oil pan.

The water in the cylinder head and around the valves is circulated by the pump. The water contained in the jackets around the cylinder sleeve is not affected by the pump, but circulates by gravity. Thus the water around the jackets does not begin to circulate until it is heated sufficiently to set up a thermo-siphon action. The water pump is of the centrifugal type, its impeller being mounted on the inner end of the fan shaft and rotating in a recess cast in the cylinder block. The shaft rotates on a Hyatt roller bearing, and is lubricated by an Alemite connection.

On the two lighter models, known as K-15 and K-16, the radiators are of the vertical fin and tube type, the tubes being assembled in connection with the cooling fins in a single unit or core. On the three larger types, K-41, K-71 and K-101, the radiators are of the vertical continuous fin and tube, built-up type, the assembly consisting of a core which is detachable as a unit, two side members, so designed as to protect the core, the top and bottom members in the form of tanks, which insure even distribution of the water throughout the entire core.

A combination manifold and carbureter have been worked out to take care of present day gasoline. Both the vertical section of the intake manifold and the venturi chamber of the carbureter are heated by exhaust gases direct from the exhaust manifold. Dampers are provided for regulating the supply of heat, and for very hot climates a gasket can be inserted which cuts out the exhaust jacketing altogether, eliminating the hot-spot and permitting operation at atmospheric temperature. A Marvel carbureter is used.

The governor is of G. M. C. design and is of the fly-ball type. It consists of four steel balls held in a steel pressing containing four separate grooves which act both as ball retainers and channels in which the balls travel. As the channels are set at approximately 45 deg. angle to the shaft of the governor, the balls travel both outward and forward under action of the centrifugal force. The balls contact with a flat steel disc, which is mounted on a bronze bushing, and as the balls are thrown outward and forward, the disc is pressed forward. This disc contacts with a ball thrust bearing, and through this bearing connects with the governor butterfly control lever on the carbureter. Lubrication of the governor is effected by the oil which is discharged on the timing gears, so that it is at all times working in an oil bath.

The Electrical System

Ignition is by an Eisemann magneto which is mounted on the generator side of the engine and is driven through a coupling from the armature shaft of the generator. On all but the smallest model the Eisemann impulse coupling is fitted. The electric generator is of G. M. C.

design, manufactured by Remy. It has been designed exclusively for truck use, being rugged to withstand pounding and hard service. The front end of the generator is cylindrical in shape and is machined to fit an opening in a portion of the timing gear housing cast integral with the cylinder block. The driving gear is mounted on the end of the armature shaft and meshes directly with one of the timing gears. This same shaft then projects through the front end of the timing gear housing and carries the pulley which drives the pump and the fan. The generator is fitted with thermostat control and third brush regulation. The thermostat control automatically varies the amount of current delivered to the battery by the generator, increasing the charging rate in cold weather and decreasing it in warm weather.

The wiring is made up in unit form. Except on the smallest models, the instruments are assembled on an aluminum instrument board with a panel which can be lowered to give access to the switch connections and terminals. No electric lights are furnished on K-15, the smallest model. The other four, however, are provided with two electric headlights and one tail light.

No material changes have been made in the clutch, which is a multiple dry disk type, with eleven disks in the two smaller models; thirteen in the 2-ton and seventeen in 3½ and 5-ton. It will be seen by reference to the accompanying cut that the transmission is of unusual design in that it incorporates two speed ranges. This is made possible by providing two pairs of constant mesh gears. The driven gears of each pair are loose on the secondary shaft but either of these can be connected to this shaft by engaging with them a positive clutch located between the two and splined to the secondary shaft. Integral with the latter are three gears arranged in conventional fashion for meshing with the sliding gears on the main shaft. It will be seen that three forward reductions are possible in combination with each of the pairs of constant mesh gears. Consequently there are, with the direct drive included, seven forward speeds obtainable. Change from one to the other pair of constant mesh gears is controlled by a separate lever. Except for this the control is conventional. The double speed range is said to have been incorporated by the addition of only four parts to the gearbox.

This double range transmission permits of the use of a higher geared rear axle, thus promoting economy, and at the same time enables a greater maximum tractive effort. It is estimated that, as compared with the previous models, the pulling power of the trucks has been increased 30 per cent, and the economy the same. A third lever is fitted for changing the constant mesh gears.

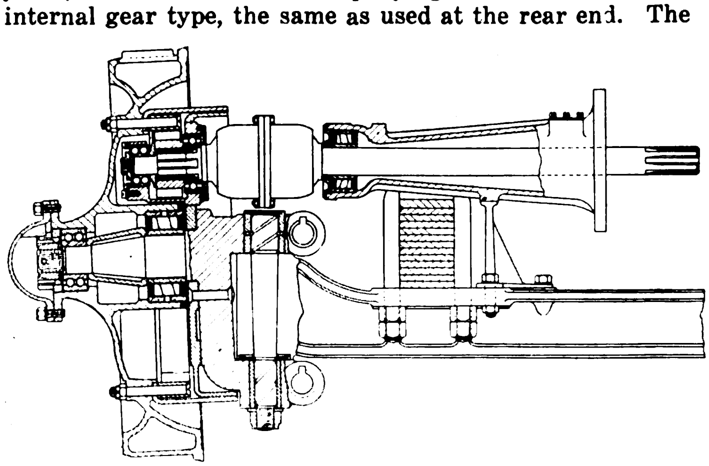
All of the G. M. C. transmissions, with the exception of that on the small model, are so designed as to enable the installation and use of both power take-off and power tire pump at the same time. The K-15, which is the smallest model, has a tire pump mounting only.

The rear axles are bevel gear-driven on the K-15 and K-16, the two smallest models, and worm-driven on the others. These rear axles have not been changed from previous G. M. C. construction, except as regards the gear ratios. The axles on the heavier models are of the Timken worm gear type. The two smaller types are equipped with steel felloe wood wheels, and the larger models are equipped with metal wheels of the hollow spoke and felloe type with the hubs cast integral. Pressed steel brake drums bolted to the inside of the wheels are used on all models. The frames are open hearth pressed steel of channel section and are all heat treated to increase the tensile strength and elastic limit of the metal. The steering gears are all of G. M. C. design and manufacture and are of the worm and split nut type. They are irreversible and adjustable, the gear being anchored in a bracket riveted to the frame and rigidly held by a heavy plate and column where it passes through the floor boards.

A Front Wheel Drive

THE most interesting feature of any four-wheel driven vehicle is the arrangement of the front drive, because the driving connection to the swiveling front wheels is the hardest problem to solve. In fact, it is in the driving connection to the front wheels that the various front-wheel drive trucks differ most.

The drive to the front wheels used on the Bollstrom truck, which has been on the market for a number of years, is shown in the accompanying cut. This is of the internal gear type, the same as used at the rear end. The axle end is of the inverted Elliot type. To the outside of the vertical part of the knuckle is secured a flanged disc similar in shape to a brake drum. This serves as support for the driving pinion bearings. The wide flange on the disc evidently makes it very rigid and gives a substantial support to the bearings. The pinion shaft is supported in ball bearings on both sides, the outer bearing (which is necessarily of limited diameter) being of the double row type.



Bollstrom front wheel drive

In order to protect the gear from mud and dust the internal gear on the cast-steel wheel is surrounded by a pressed steel drum which hugs closely the flange of the bearing supporting disc, extending across its entire width. No section of the universal joints is shown, but to judge from the length of the cover, it is a double universal, which takes care of slight mis-alignment of the center portion of the counter shaft and its ends. Felt packings are provided where the countershaft enters the gear housing in the wheel and at the inner end of the wheel hub.

THE study of the manufacture of oxygen from the point of view of the engineer is being undertaken at the Harvard Engineering School under the direction of Professor Harvey N. Davis. This study is made possible by a gift to Harvard of $5,000 from the Research Corporation, founded through the efforts of Dr. F. G. Cottrell.

Why American, British and Continental Car Designs Differ

British engineer discusses the effect of customs, climate, road conditions, taxes, operating costs, size of industry, point of view and competition upon the size, cost, appearance and design of passenger cars. Motoring here is characterized as transportation, while in Europe the spirit of adventure still dominates. Considers American braking systems defective.

By M. Olley*

THIS paper is presented rather as a record of impressions than an accumulation of facts and figures. My observations will be confined to passenger cars, with which alone I am familiar.

We will first look at the difference between the conditions in the automobile industry in Europe and America, and then consider the reasons for the difference.

The American industry is turning out large quantities of cars on a purely commercial basis. Its mind is concentrated on the ultimate consumer, and it appears to believe that the consumer rules it completely, just as the manufacturer of vacuum cleaners or sewing machines is at the mercy of the housewife.

The French and English makers are not in this position to the same extent. They do not manufacture cars in such large quantities, but to a greater extent than here each one of them supplies a strictly limited field with a specialized product of some individuality. Their profits of past years have not been entirely re-invested in enormous increases of plant and equipment and therefore, though they break and fall and rise again in new form, they are at no time quite so securely tied to the "market" as the American manufacturers.

The only qualities that their products need have, in order to sell, are that they shall transport passengers on the roads with some degree of reliability and considerable speed. Beyond this requirement there is absolute freedom.

Here, on the other hand, every manufacturer of vehicles other than motorcycles, must make something which has all the qualities of the traditional automobile —it must have an engine of at least four cylinders, almost necessarily water-cooled, with the traditional arrangement of fixings under the hood, a traditional clutch and three-speed gearbox (with the one exception) and the traditional propeller shaft to the traditional differential and live axle. Of course, it must have four wheels and a top or covered body, and the wheels even must be 56 in. apart—no more or no less. A truly crippling state of affairs.

The reasons for the differences of the industry and design of cars here and in Europe appear to me to be somewhat as follows:

First—Motoring here is transportation, pure and simple. It is rapidly coming to be the most important system of transportation in the country.

In Europe, leaving aside the recent vast increases in trucking in England, the automobile is not transportation, it is adventure. A man mounts his three horsepower motorcycle in England with the feeling of a knight-errant. Here he jumps into his four-door sedan as one boards a street car. This one fact is of the utmost importance in automobile design. One explanation of it might be that there are about ten or fifteen times as many cars here per unit of population, but I think this may be an effect rather than a cause, the car being so essential for transportation here that a vast number were produced, while the car was so unessential in Europe that it remained a rarity.

Probably the great reason for motoring being a commonplace here is the higher standard of living which brings a car within the reach of almost everyone, whereas in Europe it is still almost a luxury.

Again, in Europe the better roads, the more attractive and historical countryside (with apologies to New England), the more merciful climate, do certainly enhance the pleasure of motoring. At the same time the commuting difficulties that curse the wage-earner in this country, for some reason do not exist in Europe.

All these causes contribute toward rendering the car in Europe a vehicle of considerable romance, not merely a daily drudge, or a common household appliance.

Second—A very important factor in the automobile world in Europe is the cost of owning a car. The first cost as compared with the States is difficult to determine because of the reduced value of money, and the difficulty of assessing the true value of cars. It is best probably to take pre-war money equivalents since the value of money has decreased about equally in Europe and here, during the war.

It appears approximately true to say that a car will cost twice as much in England as in the States in proportion to living standards, and in France almost twice as much as in England.

Gasoline in England is about 80c. an imperial gallon, say 65c. a United States gallon, and in France 12 francs to 15 francs for 5 litres, or say $2.00 to $2.50 a United States gallon.

Tires appear to have fallen in price in England even more than here. In pre-war days tires there were about twice as expensive as here. Furthermore, whereas American makers understate the actual size of their tires, the European tires were far below their stated size. Perhaps as a consequence of this, the European tires will not generally give anything like as good mile-

*Paper read before the Boston Section of the Society of Automotive Engineers at Springfield, Mass., Feb. 25, 1921. The author is chief engineer of the Rolls Royce Co. of America, Ltd.

age as American tires of equivalent rating. As an example, the 895 x 150 European tire (which should be about 36 x 6) is actually the close equivalent of the American 33 x 5 both as regards size and wearing qualities.

Finally, taxation of cars is cruel in Europe, particularly England, where the tax is now one pound (nominal $5) per horsepower each year, horsepower being the rating on the cylinder diameter as in America.

Third—Another important factor, at least in England, is the fierce competition of the motorcycle continually developing upward to try and get the small car trade.

This condition affects the industry as well as the design. The motorcycle is favored by the higher cost of gasoline, tires and taxation, later average age of marriage, the habit of renting houses rather than buying them, with consequent shortage of garage space, and better roads and weather conditions. I imagine that in England there are at least two motorcycles to one car. There are seven firms making motorcycles in the States against 50 in England.

Fourth—The automobile industry in Europe is limited by the lower standards of living, by lower wages, also probably by a higher standard of thrift. The limitation of the industry has reacted upon itself in enhancing the cost of cars. It remains to be seen whether Ford and the other American invaders can break down this obstacle to development.

Another limiting factor is the distinct prejudice in the minds of many Englishmen against motorcars because they are an offense against the doctrine of "regular exercise." Many well-to-do city men in London suburbs do not own cars to this day because the weekend is devoted to exercise of one sort or another, cycling, walking, tennis or cricket, and a car might break down these regular habits.

Fifth—Design of cars in Europe is, of course, affected directly by climatic conditions, the open car being the popular model all over Western Europe, and the top, or cape-cart hood, as it is still called, being an accessory, for use only in severe weather.

Sixth—Road differences affect design differently in England and France, the national highroads of the latter country (and perhaps the racial peculiarities of the inhabitants) making speed the one essential.

Seventh—Design in England is affected greatly by the essential democracy of its inhabitants or perhaps by the fact that there the car is not the standard of the man.

Here a man will buy a car of cost proportioned accurately to his income or his pretensions.

There a cabinet minister or railroad president will own a Ford sedan, or will take pride in the possession of a miniature vehicle peculiar to the country, called a "light car" or voiturette, and resembling a traveling bath-tub. His social status is not governed by the car he drives, or by his income, but rather by the particular accent with which he speaks the English language.

Summarizing the conditions then, they are:

1—The spirit of adventure.
2—The cost.
3—The motorcycle.
4—The limited size of the industry.
5—The climate.
6—Roads.
7—The lack of definite money standards.

Surveying these governing conditions casually, one can trace the effects with fair correctness:

Condition 1—The spirit of adventure. The European motorist demands less convenience than the American. As an example, whereas the American demands electric starting and lighting, even on a Ford or motorcycle, many European small cars are content with electric light only, retaining hand starting; and many small cars, and nearly all motorcycles retain the old-fashioned gas lamp.

Generally, the American user demands that the car shall give useful service with the minimum of skill in handling, whereas the English, and still more the French, owner delights in a car which will give maximum results in the hands of a skilled driver.

Condition 2—Cost. This affects the Continent and England differently. On the Continent, though many excellent small cars are being produced, the best efforts of the trade seem to be mainly directed to the larger cars, and the automobile trade appears to have made up its mind to cater to the rich principally. In England on the contrary the middle class is having its demands met by the cars which I have called rather rudely "traveling bath-tubs."

These little cars have been continually produced in England since the earliest days but have always either perished because their cost was out of proportion to their performance or else have gradually developed into larger and more pretentious vehicles from year to year. But now the small car appears to have come in with a rush in England and it looks as though it would be the quantity production car of the future in that country, and perhaps in other countries.

These miniature vehicles, complete in every essential, are most excellent machines from every point of view for use where roads are good.

Condition 3—The motorcycle is becoming an institution in England and is used by old and young, and by both sexes almost equally.

On English roads and in English weather, it is the perfection of motoring as distinct from mere luxurious riding. The machine amounts to nothing in itself, weighs only 150 lb., is no bigger than an ordinary bicycle, travels 100 miles on a gallon of gas, yet transports you anywhere at 30 miles an hour average and 60 miles an hour maximum speed.

It can never lose its place in the affection of the British motorists, probably 80 per cent of whom have served their apprenticeship on motorcycles. It is a fine training for driving a car.

There is no hard and fast line of demarcation between motorcycles and cars in England, except in the matter of number of wheels. All vehicles of four wheels, however arranged, are classed as cars and taxed at the rate of one pound per horsepower, while vehicles having two or three wheels are all motorcycles in the official eye and are taxed independent of horsepower at a flat rate of £4 per annum with three wheels, and £3 per annum with two wheels. Hence there is a development away from the traditional motorcycle and sidecar combination to a machine which is in all respects a small car except that it drives to a single rear wheel instead of the customary two-wheeled rear axle.

These vehicles are nowadays of very excellent mechanical construction, and are entirely safe, because they are hung low. They are fast and efficient, making 50 miles or more to the gallon and up to 45 miles an hour. They cost up to £300.

The gradual development of the three-wheeler would have been a severe blow to the car makers had they not come down to meet it with small cars of even greater excellence mechanically, which can carry two or four persons in comfort at high speed, with a rated horsepower not exceeding 12 (R.A.C. rating).

These two movements, upward of the motorcycle and downward of the car, have determined the typical British car-type of the present day, coupled of course with the terrific burden of taxation and the high cost of fuel.

Condition 4—The limited size of the industry, and of the individual manufacturers, makes for higher cost, but for a more painstaking treatment both of the initial design and of the finished article. It makes for a car of more individuality, for a greater distinctiveness in each maker's designs, and for a greater receptiveness to designs which are highly unconventional.

It is well known that where output is restricted, the product is likely to have, and may safely have, more individuality than where output is great.

In other words, the design of the average European car is largely controlled by the Engineering Department, whereas the design of the American automobile is principally controlled by the buying public through the sales organization. In the main, this seems the explanation of the great similarity of American cars as compared with European.

Minor points of individuality are emphasized in the American advertising, which would pass unnoticed in the advertisements of a European car, in which the public would assume that there were many points of design differing radically from other cars.

Condition 5—The climate is chiefly felt in body design. There is a positive prejudice against permanently covered cars, except in the most luxurious types. The top is still only an emergency affair of waterproof canvas, and is only put up for severe rain storms.

Wings and skirting panels are less complete than in America, and the protection against mud and wet is not nearly so advanced. Generally, the weatherproofness of European cars is less perfect than American cars.

In the mechanism of the car the chief effect is that control of the water temperature has not attracted so much attention as in the States, and less care is taken on the average European car to insure an effortless start in cold weather. When night temperatures very seldom fall below 27 deg. Fahr., one can understand that a car designed purely for use in England and employing fuel far superior to American gasoline, need make little provision for forced vaporization.

The Rolls-Royce practice of fitting a vaporizing primer and regulatable jets is quite exceptional in England and purely due to its cosmopolitan use.

Condition 6—Roads. In England the road surfaces are excellent—even now, after years of neglect, the roads are still excellent whatever the English themselves may say. The moist, temperate climate keeps a water-bound macadam road in perfect condition almost forever without repair, so long as the traffic is not too heavy.

But the grades are heavy, the roads have just grown rather than been planned, and hence there are few straight stretches and few easy hills and most of the roads are narrow. The old coaching turnpikes, and occasional vestiges of the old Roman "streets" are the only exceptions. Because of the hedgerows, blind corners and hidden crossroads are the rule rather than the exception.

As a result, "handiness" is essential, cars must run well on top gear at all reasonable speeds and on all ordinary grades, and brakes must be above suspicion, ready for instant call.

In France there are three sorts of roads, the national highways, which are perfect motoring roads in every sense of the term, the secondary roads which are the opposite, and the cobbles in the towns and villages which are atrocious. The result is seen in French car design.

Speed for the national highways is the first consideration. Roaring, noisy motors which will make 4000 revolutions without flinching for hours on end; carbureters, which may or may not give flexibility, must be of the "straight-through" type, offering no obstruction to the inlet gas, and brakes, often on all four wheels, which will pull up a speeding car in a minimum distance, are demanded.

For the by-roads and city streets, with unflexible carbureters, there must be four speeds, a powerful clutch brake, an easy change lever, and plenty of slack in the transmission gears, so that the lever can be crashed over, up or down, at all speeds, without care or effort. There must be stiff springs and a sturdy framework both for high speed and for city cobblestones.

The average Continental car on English byways is uncomfortable to drive, uncomfortable to ride in, rough and noisy. But on Continental roads, it is in its element and shows to advantage, if one is a courageous speedhound.

American road conditions, now happily passing, have called for a car which can "go anywhere in high." Hence the low axle ratios, large engines, small high-velocity induction systems, and other features which cause the typical American car to "waste its sweetness on the desert air" at all speeds above 25 miles an hour.

The American car is the most convenient vehicle in the world to start, and to drive; it is the best able to get any place whether there is a road there or not; it is the paradise of the lazy driver. It is all-the-year-round transportation with the minimum of grief. But it is not a speed monster; it is not pleasant to steer (with certain exceptions) and its brakes are deplorable.

Condition 7—Price standards. In America one is proud. If one has a car it must be a real car, or at least look like one. It must be of such a size that the human figure does not noticeably overlap the edges. Makers of the smaller cars, in the illustrations of their advertising matter, fill their cars with pigmies to enhance the impression of reality. To agree with the illustrations of my own car, I should be not more than four foot six inches tall.

The American buying public is assumed to have formed its standards. It expects, or the manufacturers assume that it expects, just the same main features in a $1,000 car as in an $8,000 car.

In France, and the Continent generally, the fully fledged car is generally for the rich, and as such is complete and rather conventional. It is also distinctly expensive.

There have always been "voiturettes" in France, of one cylinder or more, but they have never been regarded very seriously and actually do not call for a full driver's license for permission to operate.

In England there are no accepted standards of design. The two standards of practice are only speed and economy. Until recently there were numbers of single cylinder cars. Now these have ceased, but an engine may have two, three, four, five, six or eight cylinders; it may be air or water-cooled; horizontal, vertical, Vee or radial.

The transmission may be of two, three, or four speeds, or, in a number of small cars, by friction discs and gears, or chains to the back axle. Chain, propeller shaft or Vee belt may be used. Hotchkiss drive or torque tube, differential gear or none, back axle or single wheel—all are acceptable to the buying public.

The actual size and shape of the cars vary enormously. The three-wheelers generally have the single wheel behind, but at least one has two wheels on one side

and one on the other. The track width of four-wheelers varies from 42 in. to 58, and the wheelbase from 80 in. to 150 in.

The tire sizes on cars vary from 27 x 2½ to 35 x 5, and wheels may be wood, steel-spoked, wire or disc. Wire wheels are in the majority.

Starting may be electrical or unassisted. Lighting, by electricity or gas; ignition, however, is at present almost universally by magneto, but the battery is slowly gaining ground.

External appearance is uncontrolled and varies from the extremely dignified to the extremely weird, and from the utmost symmetry to an indescribable lopsidedness. Among the miniature cars some most beautiful proportions are to be found, while many bodies fitted on large cars would attract jeering crowds in the States. The reverse is equally true.

As regards color, England and Europe generally demands the full run of the spectroscope. To European eyes all American cars are black. Bear in mind that anyone may ride in the most peculiar or tiniest of these cars without loss of dignity, and you will see how free and untrammelled is the scope of automobile design in England.

Perhaps what I have already said will serve to show the conditions which American cars have to meet in Europe. American cars have sold and are still selling in Europe in large numbers because they have a great reputation for reliability, and they can always be bought from stock, but they do not show to such a great advantage in Europe as in America.

The reason for this is that their engines are too big for the performance obtained from the car. (I am speaking, of course, from the European point of view). In other words, they consume too much gas.

Perhaps the following table of average dimensions will illustrate this:

Average Particulars of Cars

	American	English	Continental
Cylinders	6 (58%)	4 (69%)	4 (80%)
Horsepower (N. A. C. C. rating)	26	13.8	15.5
Bore, in.	3.4	2.95	3.1
Stroke, in.	5	4.75	5.1
Stroke Bore Ratio	1.45	1.6	1.65
Wheel track, in.	56 (All standard)	51 (42-58 range)	53 (40-56 range)
Wheelbase, in.	122	115 (88-150 range)	122 (86-146 range)
Axle Ratio	4.5	4.15	...
Number of passengers	6	3	...
Weight of chassis	...	1,800 lbs.	...
Weight of complete car, lb., probably about	3,000	2,300 (Many cars 1,500-1,700 complete)	...
Price	$2,794	£610	...

In France a number of cars are developing on American lines, unit construction, battery ignition, smooth external appearance, detachable cylinder heads, left-hand steering, and a host of detail fittings are making them appear more and more like American cars. Where they differ is in having greater speed, less top gear flexibility, but better brakes.

I cannot find the average price of French cars but imagine that the rate of exchange, import duty, etc., make competition from this side very difficult.

The American car probably is at a disadvantage in its quality of finish and the detail design of its mechanical parts, which have always looked rough and ready to the European eye. Its lower maximum speed would count against it.

Since on the Continent cars are run only by people of some wealth, the tax and fuel consumption of American cars are not insuperable objections.

To judge by pre-war experience, the smaller Continental cars are lacking in completeness, convenience and mechanical perfection. For example, the Continental designer has always appeared to lose patience when he gets to such details as the controls—accelerator connections are liable to consist of the fewest possible pieces of bent wire, and to be unreliable in proportion.

It is in England that the more interesting conditions exist. Here there has always been an admiration of the low-priced American cars, and from the first days manufacturers have been striving to evolve a low-priced car for the English market. The "£100 car" has become almost a slogan.

The failure to produce a really low-priced car has been largely due to the fact that English makers have not realized that a really good inexpensive car can only be made by quantity production, and that it was a matter of capital and tools rather than design.

The attempts at low-price have failed because they have "cut corners" in design, and produced something which either was not safe or was so unlike a real car as to be unacceptable even to the catholic taste of the country.

Now, with enormous taxation on horsepower and expensive gasoline, the conditions have changed and the English manufacturer should be able to meet American competition with a car which is perhaps a little more expensive than the imported cars in first cost, but is ever so much more economical to run, smaller, handier, with better brakes, better external appearance and generally more suitable to the local conditions. And in this respect, it is interesting to consider the following table taken from an English motor paper (**Motor, Jan. 12**):

Cost of Operation of British Cars

	Four Seater 16 hp. to 20 hp.	Four Seater Small Car	Two Seater Light Car	Four Wheel Cycle Car	Three Wheel Cycle Car
Weight (lbs.)	2,800-3,300	1,800	1,600	1,350	Under 800 lbs.
Tax	$75-100	$50-70	$50	$50	$20
Gasoline, gal. per year	300	240	199	132	102
Miles per gal.	20	27	30	45	60
Costs, gasoline	$220	$160	$145	$90	$74
Tire cost	$150	$90	$75	$60	$50
Oil, mi. per gal.	500	700	1,000	700	700
Costs, oil	$25	$17	$12	$17	$17
Total cost per year	$470	$317	$282	$217	$161
Cost per person carried on assumption of full use of seats	$117	$80	$141	$110	$80

Since the four-seater cars can be assumed to carry not more than two persons on the average, it is safe to double the cost per passenger in the two first cases.

It will be seen that the ordinary American car even of the smallest class would be at least as expensive to run in England as the most expensive type quoted.

It seems to me that England is on the point of solving its transportation problems in an effective manner. It seems also that in view of the fuel consumptions quoted, England is achieving real fuel economy, and it becomes a question whether this country might not attempt to develop on similar lines.

Surely, as a first step to fuel economy, it would be

logical to reduce the horsepower of American cars by 50 or at least 30 per cent, while leaving the axle ratio unchanged or even raising it considerably, and gaining flexibility by reduction in weight and improved carbureter design. Perhaps also by four-speed gearboxes.

It may be objected that it would be necessary to come off top speed more often, but the English light cars only have to use the gears very occasionally in ordinary running conditions, to judge by the reports of trial runs, unless exceptional grades are met, and grades in England are very much worse than here.

Objections to a wheel-track less than the traditional 56 in. are often heard. The first is that the car rocks sideways more with a narrow than with a wider track. I do not think this is so on road surfaces where reasonable speeds can be kept up. The 7-ft. gage railroads in England were proved to roll more than the 56½-in. gage, and narrow gage railroads show good riding qualities. The same argument applies to narrow gage cars on decent roads.

The objection that the narrow cars will not fit the ruts made by other cars on dirt roads or snow, I think cuts both ways. Personally, on a light car I would rather not have both wheels in the ruts at the same time. In the same way street car lines are safer to a car the track of which does not fit them.

As regards road conditions, these are certainly bad in the States as a whole but are rapidly improving, and in the Eastern states are becoming similar to English roads. I believe a light car of European design would perform very well on the ordinary roads of Massachusetts.

With reference to snow conditions, such as we have had in the past week, a narrow track would certainly not be an unmixed blessing, but I have the idea that a small car with a low bottom gear, not too much forward weight, and a really good control of the back axle would push its way through most obstacles, particularly if the road clearance were kept fairly high by sloping the transmission and using small back axle gears. Four speeds would be almost a necessity.

Engine Practice

Many European cars are built around the engine, and in fact in some of them the designer's interest appears to have waned after the engine was completed. This was a real failing of many pre-war cars.

One notices a real attempt to raise the mean effective pressure in European cars, by increased compression, inlet valve opening and induction systems. The valve in head engine is coming in with a certain hesitation, generally with a detachable head.

In at least one case of a detachable head, screwed plugs are still used over the valves. This seems good since with the detachable head, although the operation of cleaning the cylinder is made easier, there is far greater difficulty in making a quick inspection of the cylinder and valves than with the older type of non-detachable head with screwed plugs over the valves. Also, it is more necessary to inspect the interior of the cylinder when a detachable head is used because of the danger of internal water leaks.

With the ordinary type of detachable head, when once the head is detached and replaced, there is a constant fear in one's mind as to what sort of joint has been made, and the only way to find out is to detach the head again, and so on "ad infinitum."

In a large number of detachable head designs, the camshaft is on top, following aero engine practice.

The contrary school is still vastly in the majority, proving by excellent examples that a well designed L-head engine can be as efficient and as free from detonation as the valve in head.

At Olympia, two-thirds of the engines were four-cylinder, and over half the remainder were six. The two cylinder horizontal opposed engine is gaining much favor for light cars, this being a development of motorcycle design.

Air-cooling is only considered for small cars, probably because the danger of freezing is practically not existent in Europe.

Magneto ignition still holds the field in Europe by an enormous majority, but certain makers have been tempted by the very excellent American battery-ignition systems, to abandon their old loves, probably as a matter of justified economy. On small cars without self-starter, the magneto is almost universal and seems correct, since in this way the car can always get home, battery or no battery. So long as an engine is free enough to be started by hand on the magneto, there is a real advantage in having one, at least as a second string.

The battery ignition wires and apparatus extend over half of the car and a number of things are liable to happen to the wires and terminals in inaccessible places, which may take endless trouble to put right. In magneto ignition the only wires are the high tension leads to the plugs, failures of which affect one plug at a time and are easily traced, and one ground wire (which is sometimes omitted on European cars). This wire, if it breaks, will not stop the engine but will prevent its being stopped. If it is grounded it is only necessary to pull it off. Hence the European faith in the magneto, which will take a lot of shaking.

Clutches are about evenly divided between cone and plate in Europe, whereas in America the plate clutch is in a large majority. Perhaps this is accounted for by the excellent cone facing fabrics which one can obtain in Europe, and in America by the cheapness of manufacturing a plate clutch from pressings. In America it is necessary to have a clutch which will slip longer without burning, because of snow, and a multiple plate clutch is good in this respect of course, but not better than a cone clutch with heat proof facing, which is more liable to keep cool than a pack of disks.

Gear boxes have four speeds on 80 per cent of Continental cars and 50 per cent of English cars, even on a large number of the small cars. The advantage of four speeds, particularly on small cars, is evident and might be considered, one would think, for America, if the public could be educated to it. For small powers, the extra weight of a four-speed box is not great, and the speeds are needed. With a decent clutch and carbureter, the car should start on second and climb most hills on top or third, but first speed is good for emergencies.

Gear boxes are being combined more and more with the engine on European cars, particularly the small cars. But in England the majority of gear boxes taken over all cars are still independent and fixed to the chassis behind the engine, 70 per cent being fixed in this way. On the Continent about 50 per cent are fixed to the chassis and 50 per cent to the engine, and the latter method is on the increase.

Some of the English light cars using two-cylinder engines of the horizontal opposed type, combine the clutch casing and gear box with the crankchamber in a very neat form, in such a way that the whole of the working mechanism of the car is accessible by merely raising the bonnet.

Spiral bevels are coming in in a flood, and are not only ousting the straight bevel, but also the worm, which before the war seemed to be gaining favor rapidly. The

spiral bevel is undoubtedly one of the biggest contributions to automobile design since the Bilgram bevel planer.

Springs are almost always half elliptic on the front axle. At the rear there has been a landslide for the quarter elliptic and cantilever, which were fitted on 70 per cent of the cars shown at Olympia.

The half elliptic springs, so popular here, are fitted on less than one-sixth of the European cars, if one may judge by the recent shows.

Since the cantilever spring implies some sort of effective control of the back axle, the movement in this direction seems to be good. The torque tube or other axle control scheme seems too short in many European cars to be really good. In most of them it would have been possible to lengthen it considerably, with advantages in riding qualities and in holding the road.

Some of the European cars retain the fork joint at the head of the torque tube without provision for side movement of the axle, but most makers seem to realize that this is wrong and use a sphere or other universal device.

In general, it may be said that one or two torque tube designs which have recently appeared in the States are far better than the general run of the new European designs, both as regards mechanics and appearance.

Differentials—Several of the lighter English cars omit the differential altogether, and either drive on one wheel or drive both wheels through a rigid axle shaft. This practice does not appear to ruin the tires on a car of 2000 lb. or less, and is worthy of consideration in the States because of its great advantage in mud or snow. America has better tires at a lower price than Europe, which is an additional reason why America should consider dropping the differential on small cars.

Brakes—On this subject American design seems to be at a standstill, and European design better almost without exception. The good point about the American design is that both brakes are generally on the rear wheels, but this is cancelled in most cases by lack of an equalizing device.

The bad points appear to be that the external brake, which is relied on to do the work, is in effect little more than the old-fashioned strap brake tried and abandoned on bicycles. It is likely to grab, is only approximately balanced, is unequal in its application, springs a great deal before it really gets hold, is exposed to all the winds that blow and yet will heat up almost immediately. On very few cars does it ever really come free.

The internal, or so-called "emergency" brake, is generally no more than an enlarged piston ring and is best disregarded.

The smell of rubber and burnt string on any American highroad hill in the touring season is sufficient criticism of the local brake design, and the columns of the newspapers are its condemnation.

The means of applying the brakes too often consist of bent wire, and other things that spring, so that the driver cannot tell the moment at which his brakes make contact and simply keeps on pressing with his foot in the hope that something will happen soon. When it does, it often skids the wheels because the bands after slipping for a time have grabbed. Shrieking brakes are a minor symptom.

Brake facings in America do not appear to be the equal in wearing quality of those used in Europe.

The use of rods to the back axle instead of steel strip or cable, leads to rattling and frequent breakage.

One would imagine that the double internal expanding brake so often used in Europe could be made cheaper to manufacture than the general form of American band brake, since it consists of fewer parts and is a machine job from start to finish. It is better because it is weatherproof, will not run so hot, is more definite in its application, balances better and is more readily adjustable.

The side-by-side variety implies a wide drum, but a new type which is appearing lately, consisting of a single width drum with four internal shoes, each working on a quarter of the circumference, and controlled, one pair by the pedal and one pair by the lever, seems to solve this drawback.

Pressed drums can be used, but should be flanged outward on the inner edge for stiffness and cooling, and should be bored or ground to run true.

I wish to suggest that improvements on the lines suggested would form a great step forward in American cars.

Bodies—Much adverse criticism of American bodies has recently appeared in the English technical press, but when one examines it one finds that it applies wholly to the open-touring bodies, to which I imagine American manufacturers have not given much attention lately.

Recent American open bodies have aimed too much at sporting lines to be comfortable—they are not deep enough and the seating is too upright. I think the designs which are now criticized in Europe came originally from Europe in a number of cases. Europe now, however, has reverted to deep, comfortable, open bodies, such as were standard in this country before the war, using them all the year round, and therefore demanding the utmost of usefulness and comfort.

As regards closed bodies, however, this country undoubtedly leads by a very long margin in detail finish, in accessories, and one cannot help feeling, in general lines also.

The recent developments in quantity production of closed coach built bodies form another notable advance for which the States is responsible, and the quality of workmanship and material in these closed jobs seems to be at least as good as much of the custom coachwork of Europe.

America showed that the automobile was not the monopoly of the rich, and is now showing that true comfort in the automobile is equally available to the man in the street. In other words, what the public wants, it shall have.

The quantity production of coachbuilt bodies is a great step in advance, not only because of low price. By quantity production coachbuilding is lifted from an art to a mechanical science. It has been shown that wood can be worked accurately to make interchangeable parts, that it is capable of proper heat-treatment, like metal, and that results can be guaranteed.

The individual coachbuilt body is often a nuisance to the manufacturer of the chassis and the owner of the car, because it is so often found that in some particular the bodywork clashes with the mechanism of the chassis, or vice versa. By the quantity production of bodies such interference can be rooted out in the first experimental sets, electric wiring can be standardized, and a whole host of minor annoyances can thus be avoided.

Probably in Europe the open car will always hold the field because of the difference in climate. In any case, any form of covering for European cars will have to be truly collapsible.

Perhaps America will now show that a really convertible job can be produced in quantities, which will not rattle and which can be thrown wide open in the fine weather, and covered again by two persons in five minutes.

European, and particularly English, closed body designs appear to be going through a phase which one hopes may be temporary. The rear end of a number of English bodies resembles the rear end of a sausage in general design. I refer to the excessively rounded designs which are so popular in England just now and which appear so hideous to American eyes.

In touring cars the European designs are almost uniformly good, except that in some cases the desire for a disappearing hood has spoilt the lines of the car.

Aluminum sheet is now used extensively in European body work, but the treatment is not as complete as in American bodies, and exposed wood joints are used in window framings, etc., which are likely to give trouble in the event of a change of climate.

Aluminum roofs, used to obtain the rounded designs referred to above, are not satisfactory in many instances, as they tend to boom badly and they make the interior uncomfortably hot in summer weather.

As a summary I wish to emphasize the following points:

1. The use of cars is radically different on the two sides of the Atlantic, and selling points which are vital to the American public, such as self-starters, transmission locks, service organizations, etc., are of secondary importance in Europe.
2. The cost of running a car is greater in Europe and the roads are good; therefore, cars are growing smaller, and it is the small car above all things which appeals to the general public, especially in England.
   If America wishes to hold a big trade in England, she must evolve small, fast, economical cars of the utmost refinement as regards mechanical parts.
3. American bodywork, as known in Europe, is unsatisfactory. But actually American bodywork, as a whole, is of a higher quality than the European. It only remains for America to turn her attention again to producing comfortable touring bodies, for her to meet European requirements absolutely in this respect.
4. American brakes need entire redesigning from the pedal or lever to the back axle, if they are to meet European ideas. The idea of the hand brake being an "emergency" brake must be eradicated. If it is only to be used in emergency, the driver never accustoms himself to use it, and in an emergency it is never ready.
   It is immensely better to call it a hand brake, make it adjustable for wear and build it for use. It only remains to train drivers to use it frequently on all long hills, and it will then be used in emergency and may prevent a lot of accidents.
5. As regards detail design, Europe does not appear to know anything that America doesn't know. With the exception of the overhead camshaft engines, the small horizontal two-cylinder engines, the Argyll single sleeve and the Ricardo trunk piston, every European design is reflected strongly in the States.
6. If America were to build light cars on European lines for export, I believe they would be found to sell in large numbers in the eastern part of the United States, where road conditions are ready for them.
   These cars must not be built for use in cities only, however—they must have the speed and capacity for touring equal to the largest cars built in this country.

Finally

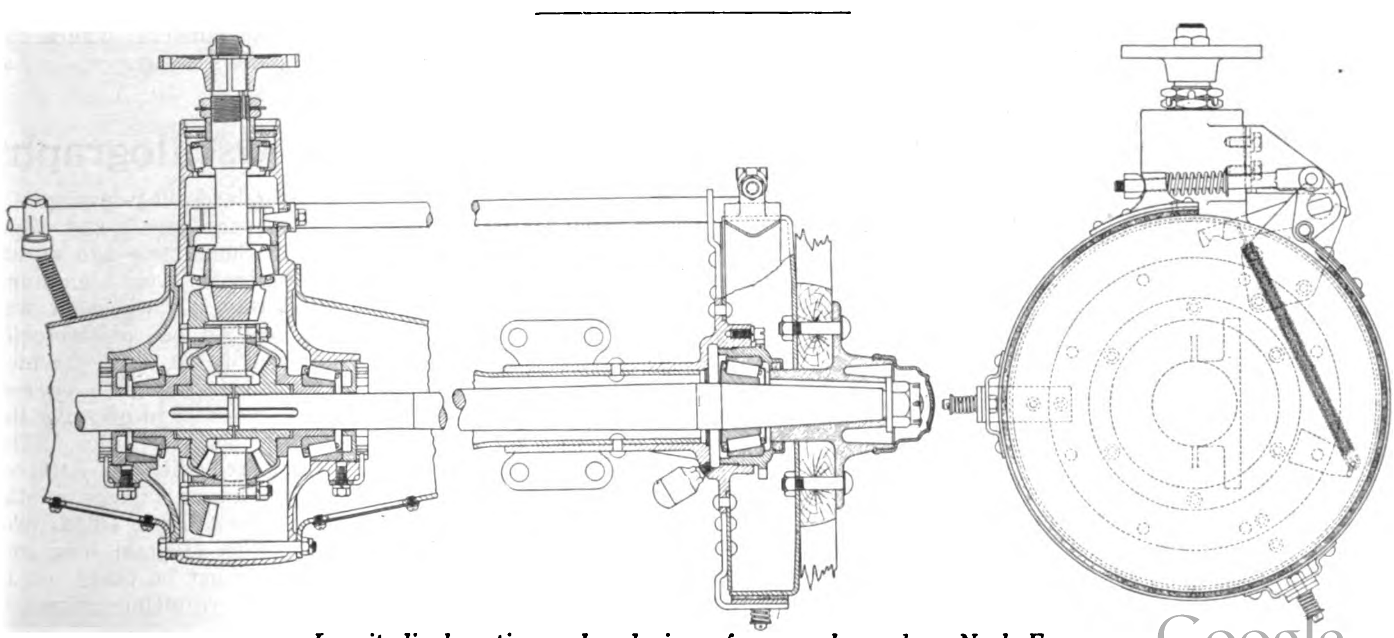
The outlook for American cars all the world over appears to me to be particularly good, because the States is now aiming not only at production, but at the production of high quality designs.

In recent American designs, equal compression volumes are often insured by machining the heads, six-cylinder crankshafts have seven bearings and are finished all over in the circular grinder, pressure lubrication is used for all moving parts of the engine, and in all ways the highest practice is aimed at, combined with strictly mechanical methods.

Other countries are trying to get the costs down, while America, having got the costs down, is trying to get quality up without increasing the costs.

It seems to me that it only remains for America to produce cars strictly suitable for European conditions, to gain a firm place in the esteem of European users.

There is no doubt that having gained a place in the regard of the European public, American salesmanship and service organization will see that the place is retained.



Longitudinal section and end view of rear axle used on Nash Four

Elbow Lines of European Cars

Many methods employed in finishing off top edge of body sides. General tendency is toward construction in which side panel is continued over the top edge to meet the upholstery. Padded top edge is disappearing.

By M. W. Bourdon

MANY efforts on the part of body builders to provide something distinctive in the top edge or elbow line are to be seen on European cars, and the accompanying sketches serve to indicate how widely diverse have been the aims and ideas of various designers.

The bolster-like effect produced, as shown in Fig. 1, by continuing the upholstery fully padded over the top edge, a finish at one time so popular, occurs very infrequently and its decline is not regretted from a practical point of view, as obviously with the full "freeboard" represented by a height of 10 to 14 in. from uncompressed cushion to top edge no use could be made of the padding as an elbow rest.

The general tendency is toward the finish shown in Fig. 2, where the side panel is continued over the top to meet the upholstery. There are a few instances where the latter cannot be seen from outside the car even when viewed from above at an angle of say 45 deg.; but this full extension of the panel has not found much favor, the general endeavor being to interpose a certain amount of padding between the unyielding parts and the passengers, even at this height. This endeavor is more or less apparent in all standard jobs, though in the "sporting" type of body the comfort of the occupants is sacrificed, presumably to obtain a racy effect.

Many body designers are reluctant to discard entirely the padding continuation to the outside edge; Humber and Arrol Johnston go so far as indicated in Figs. 3 and 4 respectively. In both cases the junction between leather lining and panel is finished off by a lead-filled metal beading, Humber securing the lining with pins into the frame and interposing a double strip of leather binding which has a small roll formed by its fold projecting below the metal bead. Angus Sanderson (Fig. 5), on the other hand, eliminates the metallic beading and finishes off the lining edge with a strip of fabric binding secured by leather covered gimp tacks, an arrangement liable to become distinctly "shabby" after comparatively short use. The sketch shows the distinct roll of the upholstery inside the top edge favored by this maker. A similar roll is used on Vinot bodywork (Fig. 6), but in this case a solid aluminum strip covers the joint of leather and inturned panel, the strip being black enameled.

A peculiar design is that on D. F. P. bodies, shown in Fig. 7, there being a pronounced step down from the top of the upholstery to the curved-in top of the panel. The latter has a vertical extension to meet the outer edge of the lining, and a double roll of patent leather binding to cover the joint. This arrangement has the clumsy appearance of the bolster edge (Fig. 1) and is without advantages over simpler constructions.

The F. N. design (Fig. 8) can hardly be considered ideal for, if the panel is finished at the outside edge vibration and distortion of the framework must obviously break the paint at the joint and cause an unsightly crack to occur. If the flat band be formed of a separate strip of metal welded on to the side panel, a comparatively expensive job would result. It must be admitted, nevertheless, that so far as appearance goes this finish has points in its favor, though the sharp outer edge would hardly be serviceable under rough usage, and there are other designs which appeal more forcibly even in appearance.

The edging used on the Phoenix body (Fig. 9) gives a neat and distinctive finish, with a simpler form of panel than is needed when the latter is rolled over to meet the lining. The panel finishes under the lead-filled beading, the rounded top edge being a moulding of wood secured to the framing. The arrangement shown in Fig. 10 (Swift) somewhat resembles the Phoenix in utilizing a moulding above the frame to carry over from panel to lining, but here a solid aluminum bead is screwed on to form the uppermost edge. This design is not so sightly as the Phoenix, for the inclined flat "band" does not harmonize with anything; it clashes with the curvature of the panels and the outline of the body.

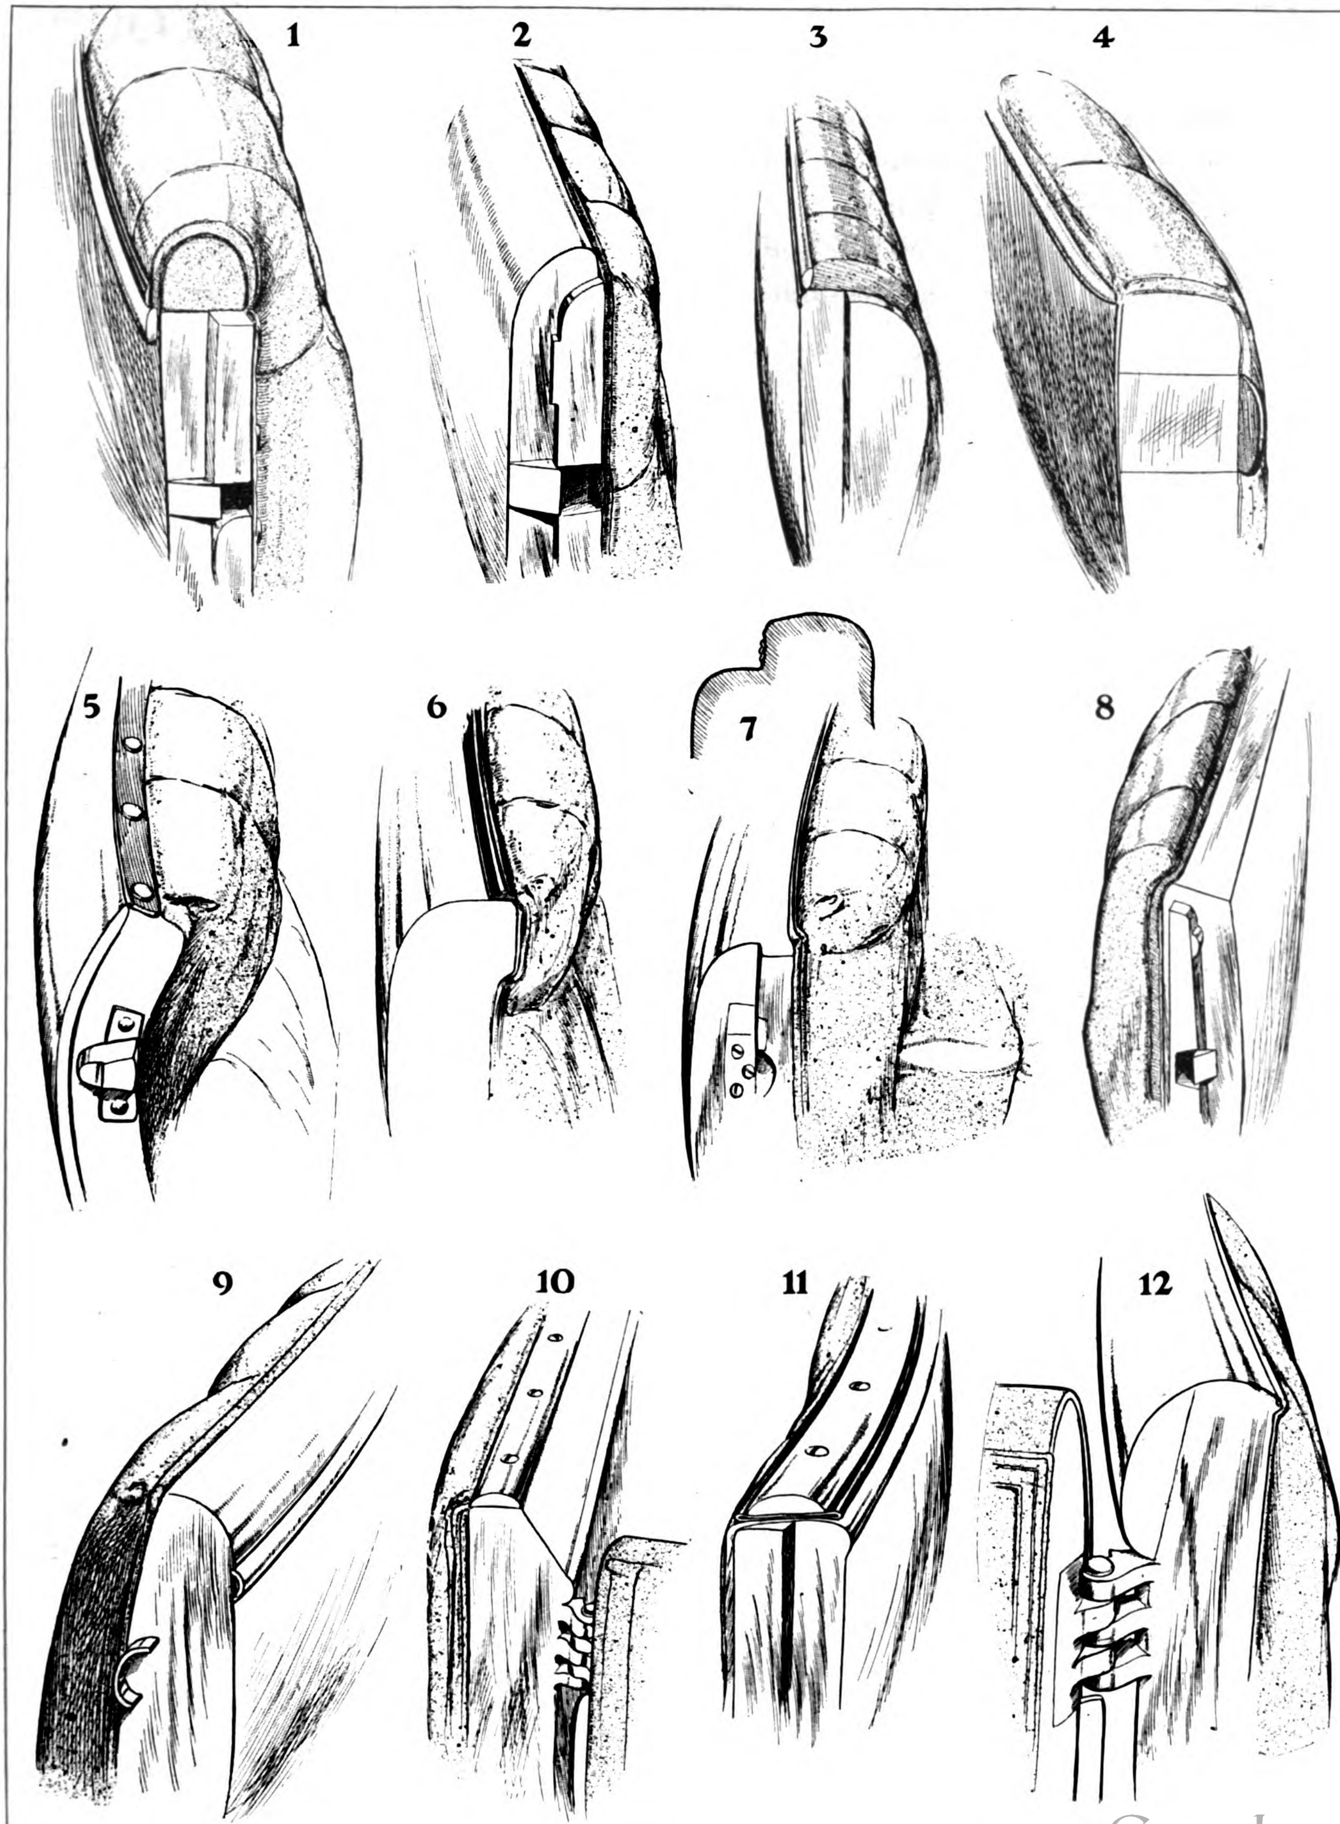
The Hillman design (Fig. 11) also embodies a polished aluminum band with a doubled leather strip beneath it to form a beading on either side. But this scheme looks cold and the "relief" it affords is not called for.

In Fig. 12 an idea is given of the Armstrong-Siddeley top edging. The panel finishes under the broad (2½ in.) half-round moulding, the latter secured to the outside of the top edge of the body framing. This moulding is finished in a slightly darker shade of paint and is a prominent feature of the body—rather too pronounced in the opinion of some people and tending to break up the lines of the body when, as in this case, it is used also (though of less width) at the corners, where the vertical joints of side and back panels occur.

Light Mirrors for Oscillographs

RECENTLY the Bureau of Standards has developed a new method for producing very small and light mirrors for use on oscillographs. Some time ago an attempt was made to produce these mirrors from aluminum, polishing the metal in the usual way. However, it was found that the metal was too soft to be satisfactorily polished and some other means had to be devised which would give a better and at the same time as light a mirror. The process, as finally worked out, consists in pressing the aluminum between two optically flat steel dies. The mirrors thus made are highly polished with the surfaces sufficiently plane to produce satisfactory images of the spot of light. The dimensions of the mirrors so far produced are approximately ½ mm. wide, 1½ mm. long, and .10 to .20 mm. in thickness. Care must be taken not to use too much pressure, as then the resulting mirror is so thin that it will not retain its plane surfaces.

Examples of Finish Used on Top Edge of European Car Bodies



Rust Prevention by Browning Process

Has been used extensively for many years for treating component parts of small arms. Produces a bluish black finish which is rendered dull by sand blasting or may be polished by buffing. Finish does not rub off, is not easily scratched and resists rust to a marked degree. Specifications for preparation of solutions and methods of application are given.

By W. C. Marshall*

IN looking over the back numbers of a prominent automobile periodical recently, the writer came across an article on rust prevention and read it with great interest. Much to my astonishment, no mention was made of the Browning process, although the process is old and used extensively by small arms manufacturers for treating barrels and component parts of small arms.

Having been connected with the works of a company manufacturing small arms in the capacity of research engineer, it fell to my lot to investigate the Browning process used in this plant and make recommendations for any changes. There had been considerable trouble in the browning room, and many rejections on account of poor browning, which the foreman said was caused by the weather. This was true to a very limited extent, because the browning depended principally on atmospheric conditions in this plant. Humidity is very necessary, either controlled or natural. In the above case it was a combination of both, the artificial regulation depending on the foreman, who did not believe in control and preferred to go by his own feelings in the matter of humidity. The time required for the whole process at this time was 96 hours. The first step in the investigation was to install automatic control of temperature and humidity and instruct the foreman to keep his hands off the valves. Recording instruments were installed to show how temperatures varied, and soon the system was working satisfactorily so far as the actual process went. The only failures thereafter recorded were due to someone trying to assist the automatic regulators by closing valves by hand and ruining whole batches of parts.

The question of browning solutions was then taken in hand, the object being to find the cheapest solution which would do satisfactory work.

Steel in a smooth or matt condition of finish is very prone to oxidize or rust if it is exposed to moisture either from the air or from the human skin. The air may carry hygroscopic particles of sodium chloride (or salt) which are deposited on the metal surface and act as a powerful oxidating agent. The exudation from the human skin may have an acid reaction which would start oxidation at once. To prevent this action in the presence of such conditions, it has been the custom of arms manufacturers to coat their products with an artificial coat of rust which will prevent the formation of any further oxides or rust. This coat is produced by acids and the operation of rusting is named "Browning," although the color produced is bluish black and not brown as the name indicates. The finish is smooth or dull, depending on the finish of the surface of the steel before browning. A dull finish is produced by sand blasting and a glossy finish by buffing. It does not rub off, scratches with difficulty and resists the rusting tendency of the air or hands to a marked degree. It wears off *very* slowly when subjected to a rubbing action, and the writer has a golf mashie head with dull finish which was browned in 1915 and still has the bluish black color intact all over its surface except on the face and lower edge where the head cuts into the ground in playing a shot. There has been no rusting except for a little on the face, in spite of the fact that the club has been badly cared for in not being wiped off nor oiled after using.

*Consulting Engineer.

The process is adapted to all kinds of automobile trimmings, looks and wears better than most of the so-called rust preventatives, and is not expensive to use.

The operations of the browning process are as follows:

1. Thorough cleaning of the parts in a soda solution.
2. Applying the browning solution evenly.
3. Keeping the parts in a room at a fairly high temperature during the rusting process.
4. Boiling in water to reduce the high oxide of iron to a low oxide.
5. Carding or buffing the surface of the parts to remove loose particles of the oxides.

Cleaning of Parts

Cleaning of the parts is done by boiling in a solution of water and sal soda. This solution should contain from 5 per cent to 20 per cent of alkali. As an example, 7 cu. ft. of water should have 61 lb. of sal soda added to give a 5 per cent solution.

After cleaning, the objects are dried and the browning solution is applied with a brush or sponge or by dipping. They are then dried in the atmosphere, a second coating of solution is applied and allowed to dry 30 minutes, after which they are placed in a dry room heated to 170 deg. Fahr. for 30 minutes. This is done to bring them to a temperature not lower than that in the humid room in order to prevent condensation on the parts when placed in it.

The humidity of this room is kept at 60 to 70 per cent and its temperature at 160 deg. Fahr.

The work is kept here for 1½ hr., the object being to hasten the rusting under the most favorable conditions, viz., high temperature and high humidity.

At the end of the rusting period, the pieces are boiled 15 minutes in clear water, dried and carded. Then they are painted again with the browning solution, dried, heated in the dry and humid rooms, and boiled. This process is repeated twice, making five coats of browning solution in all. The whole time consumed in the process is 11 hr. 28 min., divided into 31 operations as shown in the accompanying table.

The success of all the processes depends on the cleanli-

1.	Boiled in soda water	15 m.
2.	Boiled in clean water	10 m.
3.	Cooled and dried	5 m.
4.	Painted	5 m.
5.	Dried	30 m.
6.	Painted	5 m.
7.	Dried	30 m.
8.	Dry oven	30 m.
9.	Humid room	1 hr. 30 m.
10.	Boiled	10 m.
11.	Cooled and dried	5 m.
12.	Carded and painted	5 m.
13.	Dried	10 m.
14.	Dry oven	30 m.
15.	Humid room	1 hr. 30 m.
16.	Boiled	10 m.
17.	Cooled and dried	5 m.

30.	Carded	5 m.
31.	Oiled	3 m.
		11 hr. 28 m.

ness of the surfaces and the temperature and humidity of the air during the periods of oxidation. The control of temperature and humidity should be automatic if possible, as a slip in either one means failure of the process from the standpoint of uniformity in product. Carding is also an important part of the process. The wheels used are of fiber or wire or card cloth on wheels or belts.

Solutions

Browning solutions are made by combining many different chemicals, the object being to obtain a solution which will oxidize rapidly. Some solutions are considered very secret, but, so far as the author's experience goes, they are no better than any one of the half dozen listed below, which were experimented with for competitive purposes.

Eleven different solutions were tried on eleven different pieces of buffed gun barrels, numbered as follows:

1. R No. 1
2. R No. 2
3. Exper. No. 1
4. Ponsot
5. Springfield
6. Enfield
7. Scientific Receipts
8. No. 4
9. No. 5
10. No. 6
11. Henley

The barrel samples were treated and the results in order of merit were as below. The determination of merit of the 7 good samples amounted in this case to the estimate of worth by several good judges of browning, to whom the samples were submitted. Any one of the following solutions can be used with good results, although they are arranged in their order of merit.

The cost per gallon of the solutions in 1916, based on alcohol at \$3.16 per gallon, is shown in the table below, also their cost when using denatured alcohol (in brackets) at 60 cents per gallon.

1. Springfield	\$0.90	(.77)
2. Exper. No. 1	.27	
3. No. 5	1.45	(.43)
4. R No. 2	.35	(.27)
5. R. No. 1	.30	
6. Ponsot	\$3.38	(.86)
	1.80	(Half water)
7. No. 4	.86	(.86)

The prices of other chemicals were:

Nitric acid	\$0.11	per lb.
Iron chloride	.25	" "
Hydrochloric acid	.07½	" "
Bichloride of mercury	2.38	" "

The Ponsot process used above was not the one indicated below, the solution being the same, however.

The true Ponsot process requires a dry oven heat of 248 deg. Fahr. and can be done in 6 hr. 30 min. The chemical composition of each solution is given in Table 1.

Chemistry of Browning

The chemistry involved in browning is complex, and chemists do not agree even on the simple facts. Ordinary iron rust or iron oxide is probably a mixture of ferric oxide, hydrated ferrous and ferric oxides, basic ferrous and ferric carbonates. After long exposure to the air, the amount of ferric oxide in the mixture becomes relatively large and the amount of other compounds relatively small. Rusting conditions may be varied. Dry iron in dry air will not rust, as moisture must be present before rusting can occur. It is affirmed by some that the presence of an acid and water is necessary, but this is denied by others. Evidence shows, however, that the presence of an acid is necessary for rusting.

Atmospheric rusting proceeds in the following manner. Films of moisture, holding carbonic acid and oxygen in solution, condense on the surface of iron exposed to air. An acid ferrous carbonate $Fe(HCO_3)2$ or a basic ferric carbonate $Fe(OH)_2(HCO_3)$ is first formed. The ferrous carbonate in contact with oxygen is oxidized to a basic ferric carbonate $Fe(OH)_2(HCO_3)$ or to $Fe(OH)(HCO_3)2$ or both. The basic ferric carbonate is then hydrolized by the water forming ferric hydroxide $Fe(OH)_3$, and the ferric hydroxide is subsequently more or less hydrated, forming ferric oxide.

Once rusting has started, the action is accelerated because the ferric oxide is hygroscopic. As the rusting goes on, the ferric oxide increases in quantity and with it the amount of moisture. Near the sea coast there is more or less sodium chloride in the air. This is in the form of small particles like dust. Sodium chloride is very hygroscopic; therefore, any particles of it which settle on an iron surface not only cause the above conditions, but also remain in the film as a powerful oxidizing agent.

Since atmospheric conditions are too uncertain to depend upon for commercial purposes, a combination of a number of oxidizing agents can be used in place of sodium chloride, such as oxygen, ozone, the feroxides, the oxy-acids and their salts, such as nitrous, nitric, chromic, chloric, etc., and the halogens, chlorine, bromine and sodium, permanganic acid and its salts, viz., potassium, fericyanide, etc.

Among the references used are Mellor's Modern Inorganic Chemistry, Newth's Inorganic Chemistry, and Remsen's Chemistry.

Inasmuch as the Ponsot process differs from the one described previously, it is described at length as follows in case some one desires to make use of it.

Ponsot Process

The Ponsot Process of browning produces a rapid oxidation of steel, usually by the application of two coats of a special solution.

1. Manufacture of the Special Solution.

The composition of the solution is as follows:

Nitric acid at 40 deg. Baume	65 cc.
Commercial hydrochloric acid	130 cc.
Chloride of copper	10 grams = 0.3537 oz.
Iron filings	Necessary quantity
Perchloride of iron at 45 deg. Baume	100 cc.
Commercial alcohol	2 liters = 2.113 qts.

In the dipping process the coats are applied by dipping the pieces directly into the solution.

If the coats are to be applied by means of a sponge or brush, the composition of the solution is modified by re-

placing one liter of the alcohol by one liter of water.

To prepare the solution place the chloride of copper in a porcelain vessel; on this pour the nitric acid, then the hydrochloric acid. When the copper salts are dissolved the iron filings are added in small quantities, very slowly at first and then more and more rapidly, being stirred with a glass rod. The quantity of iron filings should be sufficient completely to neutralize the acids; the reaction is complete when the red vapors become white. It is essential to use an excess of iron filings to make sure that the solution shall be completely neutral. At this time the perchloride of iron is added, then the alcohol (or the alcohol and water).

The bath is now ready for use without filtration.

Care must be taken to stir at the time of use.

2. Browning.

The necessary successive operations for browning are as follows:

(A) Cleaning components of grease or fats.

(B) Applying and fixing the first coat, comprising:

1. Applying one coat of solution by dipping or by sponge or brush.
2. Placing the pieces in dry oven at 248 deg. Fahr. (120 deg. C.) or first heat (for an average time of 20 m.).
3. Placing the pieces in steam oven at low pressure (for 20 m. exactly).
4. Placing the pieces in dry oven at 248 deg. Fahr. (120 deg. C.) or second heat (for same length of time as for first heat).
5. Placing the pieces in bath of boiling water (for at least 20m.).
6. Wiping or drying the pieces with sawdust.
7. Scratch-brushing.

(C) Applying and fixing the second coats, comprising exactly the same operations as the first coat.

(D) Greasing the pieces.

These various operations are explained in detail below.

Removing Grease and Fats From Components Before Browning

No special process is necessary. The one in use in French plants may be used, namely: Immersion of the pieces for 20 m. in a bath of boiling water containing .500 kg. (1.1 lb.) of carbonate of potash in 100 liters (26.417 gal.) of water, followed by a cleaning with whiting.

Applying the Coats of the Solution

It is important that the coats be regular and perfectly uniform. The best process is by dipping. The piece is immersed and immediately taken out with a sharp shake to prevent the formation of a drop. This precaution prevents the excessive erosion of the metal where the coat is thickest, and grooves and etchings are avoided.

The coats may be applied by means of a sponge or brush. The solution may then contain water to prevent too rapid an evaporation of the coat, which would occasion excessive thickness. The trials made at the St. Etienne factories with the sponges used in the old regulation browning process have not given good results; in spite of precautions taken to dampen the sponges, the coat was not very uniform and the pieces showed marbled surfaces. (The operators were not very expert.)

With a pure alcohol solution, the drying is instantaneous and the pieces may at once be placed in the ovens at 248 deg. Fahr. (120 deg. C).

With an aqueous solution it is necessary to wait about 30 min. so that the pieces will be dry before being put into the oven.

Placing the Components in the Dry Oven at 248 Deg. Fahr. (120 Deg. C.)

(First or Second Heating)

The oven may be of any model, the sole conditions being that it can produce a uniform heat at 248 deg. Fahr. (120 deg. C). The pieces should stay in an average time of 20 min. It is essential that only pieces having approximately the same weight be placed in the oven together so that all will heat uniformly.

The design of these ovens depends on the number of pieces they must hold.

Placing in the Steam Oven at Low Pressure

The components should be placed in this apparatus on coming out of the oven at 248 deg. Fahr. (120 deg. C.), but after a certain amount of cooling, to about 122 deg. Fahr. (50 deg. C.). It is essential that all pieces be of the same temperature at this moment, the weight of the pieces being the same. The design of the oven is determined by the number of pieces to be placed therein. A closed tank may be used, into which is poured each time a fixed quantity of boiling water. This water should be drained off after each operation.

The object of this apparatus is to produce steam at about 140 deg. Fahr. (60 deg. C) and to let the pieces cool to about 86 deg. Fahr. (30 deg. C). The parts should remain in the apparatus for 20 minutes.

Placing the Pieces in Bath of Boiling Water

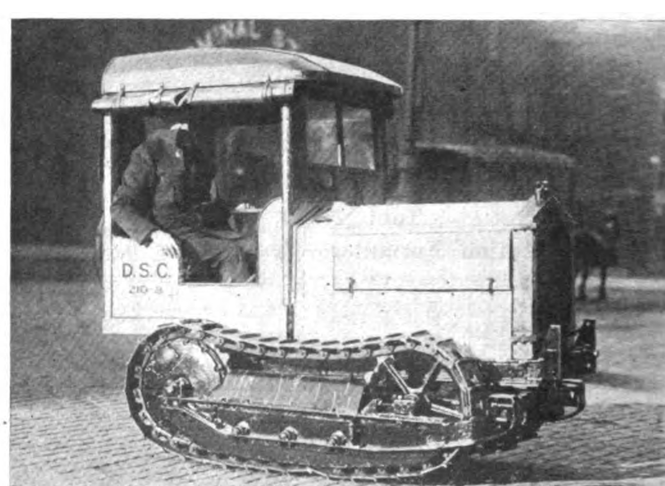
This operation is the same as in the regular Browning process, the parts remaining in the water 20 minutes.

Scratch Brushing

For this purpose it is necessary to use brushes of steel wire, the diameter of the wire not exceeding 1 mm. 0.040 in.

The detail work of the experiments was carried out by my assistant, W. D. Carpenter, and the results of their application to the work in the plant were most satisfactory in every way. The construction of cabinets or heating rooms depends on the requirements of each individual plant and the supply of air and moisture to these rooms depends on the facilities available. In any case, the control of the air supply should be automatic and positive.

Tractors in Snow Removal Service



One hundred of these Cleveland tractors were used in an effort to clear New York City streets of snow after the recent storm

Status of Commercial Aircraft Shown by Company Development

Yes, there is an actual development of commercial flying. This list of flying companies shows that there is the beginning of a transportation service in the air. Data on landing fields especially interesting.

THE fact that there are in this country 21 commercial aircraft operating companies that have flown 25,000 or more miles each will probably surprise most persons who are interested in aircraft development. Thirty companies have exceeded 1000 passengers. These figures are illuminating as to the progress made in aircraft transportation. It is interesting also to note that there is apparently a basis for charge for flight, in that the rates charged by these companies range below $1 per mile, but near that figure, although in one or two cases the charge drops as low as 60 cents per mile. It will be noted also that several of these companies are making progress in the amount of freight carried, 25,000 lbs. having been carried by one company.

The following tabulation is taken from advance proofs of the "1921 Aircraft Year Book" published by the Manufacturers' Aircraft Association, Inc.:

	Name of Company	Address	Aircraft	Air Port Facilities	Charge Short Flight	Charge Pas.-Mile Inter-City Flight	Passengers Carried	Freight Carried lbs.	Miles Flown

KEY TO AIRCRAFT AND ENGINE TYPES

50 and 50-B-2, three-place flying boats, Aeromarine engine; F.-5-L Navy Cruiser, fourteen-place flying boats, Liberty engine; built by Aeromarine Plane and Motor Company, Keyport, N. J.

B.B.-L., three-place land plane, Hall-Scott engine; B.-1, two or three-place flying boat; C, twin float seaplane; built by Boeing Airplane Company, Seattle, Wash.

J.N.'s of the various types, two-place land planes; Oriole, three-place land plane; Seagull, three-place flying boat; F. and M.F., two and three-place flying boats; Eagle, ten-place land plane; H.S. and H.-16, six to sixteen-place flying boats; OX, K and C engines; Liberty engines in larger types; built by Curtiss Aeroplane and Motor Corporation, Garden City, L. I., New York.

K.T:, two-place land plane; O.W., three-place land plane, Liberty engine; built by Dayton Wright Company, Dayton, O.

J.1 and J.-2, two and three-place land planes built by Standard Aircraft Corporation, Elizabeth, N. J., and rebuilt by Curtiss Aeroplane and Motor Corporation or others.

† indicates Wright engine built by Wright Aeronautical Corporation, Paterson, N. J.

‖ indicates Liberty engine built by Packard Motor Car Company, Detroit, Mich.

‡ indicates engine built by Hall-Scott Motor Car Company, Berkeley, Calif.

F.40 and F.46, French Farman; J.L. monoplane, German Junker; 504-K, British-Avro; * Lark monoplane; ** French Breguet; *** Daugherty tractor; °Laird landplane; °°British Bristol.

The operating companies report a total of 222 forced landings and 88 accidents.

(The above is based upon statements made to the Manufacturers Aircraft Association, Inc., in response to questionnaires sent to all known operators of aircraft. No opportunity has been available to determine the accuracy of the information and no responsibility is taken for the data except for the care with which the figures and facts are reported and the manner in which the summary is presented

Napier Cub Aircraft Engine

SOME additional details of the Napier Cub aircraft engine, referred to as the most powerful aircraft engine ever built, have come to hand. The engine has sixteen cylinders arranged in the form of an irregular cross, the two upper rows of cylinders being placed at as small an angle as possible (apparently 45 deg.) and the two lower rows making an angle of 90 deg. with the adjacent upper rows. Between the two lower rows the crankcase protrudes downwards to form a sump, and into the front end of that sump is cast the carburetor body, which comprises one float chamber and four mixing chambers—one mixing chamber for each row of cylinders. Half of the reduction gear housing is cast on the upper half of the crankcase. The cylinders are evidently very much like those of the Liberty engine, but have four slightly inclined valves in the head of each. Rocker arms protruding from the cam housing are employed for operating the valves, and a novel mechanism is said to be used for overcoming the side thrust on the valve stems which usually accompanies the use of this device. Three machined surfaces for bearing brackets are provided on the upper half of the crankcase on each side.

It is claimed that the Cub on its first test run showed an output of 1057 hp. The weight is said not to exceed one long ton, hence if the figure given is correct the engine weighs 2.24 lb. or less per nominal hp.

GREAT developments are predicted in French commercial air services, and it is understood that large grants are to be made to private enterprises engaged in the business. The Budget estimates for the present financial year are $10,660,000, and it is intended to ask for $15,550,000 for aviation requirements in the next financial year. Subsidies are to be given to companies operating services between Paris and London, Brussels, Toulouse and Monaco, and aerodrome facilities are being provided for airships and seaplanes at Marseilles, Algiers, Casablanca and Tunis, the intention being to establish services to North Africa. Consideration is also being given to the development of Constantinople as an air port.

Italian Airship Purchased by U. S. Army

THE Roma, here illustrated, is said to be the second largest semi-rigid airship in existence. It was recently purchased by the War Department from the Italian Government for $200,000. It is said that it would cost $1,250,000 to duplicate this dirigible here. The Roma is 410 ft. long and has a cruising radius at full speed of 3300 miles.

Except for the British Dirigible R-34, which is of quite different type, being, like the German Zepellins, of rigid construction, the Roma will be the largest airship to take the air over this continent.

Improved Service Obtained by Training Service Men

Every car that is sold must be kept "sold" until it stops running. The importance of service as a merchandising aid is increasing. This article describes how one large manufacturer is training competent service men for work on his product, thus insuring a uniformly high grade of service.

THIS interesting description of the work being done by one large automobile manufacturer in training service men was prepared by A. G. Bierma and read by F. J. Wells before a recent meeting of the Service Division of the N. A. C. C. It presents in detail the purposes of the course, the sources from which students are obtained, and the methods used in training them. The following transcript of the article is well worth careful attention:

The purpose of Pierce-Arrow Service Training is to supply men who are carefully selected and trained on our product, with whom to build up a competent service personnel among our distributors and thus insure as nearly as possible the uniformity and high quality of service, which is such an important factor in keeping our product sold and in making new sales.

From the practical standpoint, our training is based on the fundamental principle of educating through instruction plus practice—actual practical experience on the product under commercial conditions, plus lectures, personal instruction and examinations to insure a thorough understanding of the work covered and personal ability to handle the duties expected of the men in specific positions in our various distributors' service organizations.

From the individual's standpoint, our training is intended to give not only the mechanical knowledge required, and some skill through practice, but also personal development and the building of morale through personal contact and acquaintance with the factory, its organization and its personnel.

Sources of Candidates

Candidates for Service Training are obtained from the following sources, arranged in approximate order of greatest number of contributions:

1. From Factory fitting departments.
2. From or through direct application by letter or person.
3. From or through Employment Dept.
4. From or through Distributors.
5. From or through Roadmen and their reports.
6. From or through Advertising.
7. From or through Service Dept. Divisions.

Many of our most capable practical men have come to us from the factory fitting departments. This source has on the whole proved very satisfactory, because usually the men have been transferred on the basis of merit and more can be learned first hand of their demonstrated ability, personality and spirit.

A great many applications come through the mails from men who have either heard of our training or who know the reputation of the company and want to become associated with it. Many of these accepted have proved very satisfactory.

A few distributors and fleet owners have sent in men for regular or special training which has brought good results.

Candidates are selected through a semi-committee system. Their records of personal data and experience are first reviewed by the Director of Service Training either from the applications mailed in or by personal interview. In this way the likely candidates are separated from those unqualified. The final selections are then made or verified by conference with the members of the committee on employment and training. Adequate mechanical training and experience are required.

To insure obtaining the maximum amount of vital information, so that fair judgments may be arrived at, applicants by mail are asked to give complete information on a standard application form supplemented by a recent snapshot and a letter explaining more fully their training experience and desires.

Outline of Training

Mechanical training in shop comprises one to twelve months of productive time. Applicants, as accepted, are placed in the Factory Service Station as helpers or producers on regular production work and on regular production pay to the extent that they demonstrate their ability. They are usually placed first in the Chassis Repair division, and as they develop, showing ability, interest and the proper spirit for the work, they are pushed on through the various repair operations. When sufficiently qualified, they are transferred to the Motor Repair division, where a similar procedure is followed.

In this way experience is provided on all the important repair and fitting operations.

Toward the conclusion of the shop training those men who have shown that they possess the necessary mechanical ability, personal qualifications and right spirit toward the work, are selected for finishing training, consisting of driving, testing and trouble-shooting followed by such specializing training as may be necessary.

Service test, lasting from two to four weeks, is next given. This test is given to two to six men at a time and is available for the following groups:

(1) Men who have qualified in Productive Training Shop.

(2) Distributors' men, whose qualifications meet our requirements, when accommodations are available after taking care of regular men (1)

(3) Fleet owners' men, whose qualifications meet our requirements, when accommodations are available after taking care of regular and distributors' men, (1) and (2) above.

The work covers systematic testing, driving and trouble-shooting, as follows:

(1) Examination on mechanical work (mechanical, oral and written) as final check on mechanical qualifications.

(2) Study (disassembly and inspection) of carburetors, and electrical equipment (magnetos, distributors, switches, regulators, generators, starting motors) followed by examinations.

(3) Adjustment, tuning and testing of engines and trouble-shooting on test stand.

(4) Driving and road testing.

Final specializing training is given to such men as require it for the specific positions they seem best qualified to fill, by allowing them to act as helpers or assistants to the various men in the Factory Service Station Organization handling these specific duties; for example, prospective truck inspectors work with the local inspectors, foremen with the Service Station foremen, service salesmen with the Service Station car and truck service salesmen, service superintendent or managers with the truck inspectors, foremen, service salesmen and accountant.

To supplement the mechanical work in the shop, to afford a better basis for understanding it and to stimulate thought, study and personal development, two series of lectures are given, Shop Lectures and Service Training Lectures.

The shop lectures are open to all the men in the service station, attendance being required of those in training. Three courses are included:

(1) Construction and Operation of the Motor Car.

(2) Evolution of Design and Construction of P-A cars and trucks.

(3) Automotive Electrical Equipment—Fundamental electrical principles and applications, construction and operation.

The Service Training Lectures cover a discussion of Service Station problems, such as stock and tool keeping, repair order system, routing work, handling men, shop costs, truck inspection, etc. They are open only to the men in the finishing courses.

Progress of Men Closely Watched

The progress of the men is closely followed and checked by means of critical observation and periodic reports, conferences and examinations. Records are kept of these to assist in judging the fitness of the men and to assist the Committee on Employment and Training in the proper placing of the men when finished.

High morale, "spirit," is in large measure, the factor that determines more than any other the larger and permanent success or failure of an organization.

In our case, one purpose of service training is to infuse into the men as much as possible of a spirit of service; for the company, which is training them; for the agency or company employing them; for the customer whom he may serve.

This is partly a matter of morals and ethics and partly a matter of mutual understanding between and appreciation of men.

Means to this end, as provided by the training system, include:

1. An intimate knowledge of the factory and its product through visits to its various parts and observation of the nature and character of the work done, and the actual work done on the product as it passes through the men's own hands in the Service Station.

2. The personal attention given to each man through the various stages of his training by all the men concerned with training.

3. Personal contact and acquaintance with the Service Department personnel through interviews, conferences, lectures and occasional association in other activities.

4. Contact and acquaintance with important executive heads of the administrative personnel of the company through attendance at informal talks or get-togethers.

5. Informal get-togethers or service suppers to promote mutual acquaintance between the men and to afford contact with important factory and department executives.

6. Occasional picnics, games, etc.

Placing Men

The placing of men may be outlined as follows:

1. **Men Wanted or Required.**
   - a. For distributors, men are requested or required
     - (1) to supply men with factory training and acquaintance with the product.
     - (2) To replace men leaving.
     - (3) To fill new positions.
     - (4) To establish entire new organizations.
   - b. For Fleet Owners are requested:
     - (1) All-round mechanics for maintenance repairs, testing, trouble-shooting and emergency service.
     - (2) Truck repair master mechanics, foremen or superintendents.
   - c. For Service Department men are occasionally needed for
     - (1) District Service Representatives (Roadmen).
     - (2) Office organization.
     - (3) Factory Service Station.
   - d. Types required include Head Testers, all-round Service men, foremen and truck inspectors, Service Salesmen, Superintendents and Managers, roadmen, technical men with service experience, etc.
2. **Men Available** include
   - a. Men just completing factory service training.
   - b. Factory trained men who, for legitimate reasons, desire to make a change or having left the organization, wish to return to it.
   - c. Experienced distributors' men who, for legitimate reasons, desire to make a change or having left the organization, wish to return to it.
   - d. Experienced non-P-A men.

The greatest difficulty in successfully meeting field requirements is to have the right men available at the critical time of need. The requests or needs for men in the field are usually irregular and unexpected as to type and time required and often epidemic. Sometimes the annual averages of men required can be fairly approximated, but the time element cannot be anticipated. This is further complicated by the fact, that, although the training shop affords a small reservoir with a little flexibility, good men are so scarce that they must be accepted for training usually very close to the time when they become available rather than at any arbitrary time set by the factory; and, furthermore, nothing positive is known as to their capabilities until toward the close of their training, which extends over a period upward of nine months and cannot be fixed absolutely. The same difficulty applies to outside men; they cannot remain out of work very long, neither can a distributor, as a rule, wait very long for a man.

To facilitate the proper handling of requests, as nearly complete records as possible are kept on file by the Field Organization Department relative to the field requirements and the qualifications of the men available.

In some cases placing of men is accomplished by placing employers and men available in direct communication with one another to make their own arrangements.

In most cases, however, the placing of men is closely guided by the Field Organization Department in order to place the best qualified men in the most strategic positions and in such a way as to constantly increase the number of service stations with factory trained men in charge and to build up the service in centers important and strategic from a sales standpoint. Both men and employers usually hold the factory largely responsible for the success of these arrangements. Therefore, in all such cases, it is clearly recognized that no such arrangement can be long successful unless it is agreeable and profitable to the man, to the employer and to the Pierce-Arrow Motor Car Co. For this reason most of this work is done by conference with the members of the Committee on Employment and Training, who combine their resources of knowledge and understanding (gained through correspondence, field trips and personal contact) of the company's field needs, the nature and disposition of the employer and his organization and their needs, and the nature and disposition and other qualifications of the men.

Some idea of the value of this training may be gathered from the fact that there are now in the field service organizations of our distributors somewhere in the neighborhood of 160 men who have had a thorough factory training and are familiar with our product and who are occupying positions of more or less responsibility from that of service manager down to that of all-round service men.

Not only is this a splendid asset to the company in maintaining Pierce-Arrow service standards in the field which has had a material influence on sales, but through the maintenance of the training work the company has been enabled to fill in a number of serious breaches in our field service organizations. For example, in January, 1919, when the Cincinnati agency changed hands from the Hanauer Automobile Company to the Cunningham-Holmes Company, it became necessary to build a sales and service organization from absolutely nothing, not even a building. With the aid of the department a building was selected and leased, plans for remodeling made and the work supervised, tool equipment ordered and its installation supervised, stock equipment recommended, ordered and placed in order in the stock room and a factory trained personnel installed in the service department, including service manager, shop foreman, truck inspector and head tester, so that a going concern was provided and established even before the building was completed. Similarly in Denver in 1919 when Mr. Arthur Kumpf took over the agency from Tom Botterill, in addition to assistance with his building layout, Mr. Kumpf was provided with a shop foreman, truck inspector and tester, and an all-round service man for Colorado Springs, so that he had a working organization almost from the outset. Such complete reorganizations are not always possible unless the proper calibre of men are available at the time of need, but such results as have been attained would have been all but impossible were it not for the facilities of the training shop and its small reservoir of carefully selected and trained men.

Pierce-Arrow Service Training inaugurated originally about 1906 as a chauffeurs' school, has been in operation now for about 14 years and out of this has evolved the system as outlined.

The following is a summary of the work done during 1918 and 1919:

	1918	1919
MEN ENTERED		
Regular	33	34
Special, from agent	9	5
From owner	1	.
New men	3	2
Old men returned	7	5
	—	—
Total	53	46
MEN QUIT, DISCHARGED		
Regular	12	9
Special	1	—
	—	—
Total	13	9
MEN PLACED		
By Department		
With agent	18	26
With owner	3	2
With factory departments	12	9
Returned to		
Agent	9	5
Owner	1	—
	—	—
Total	43	42

From this it will be seen that the present average rate of output is about forty-two men per year.

At the present time there are some ninety-one places where recognized service is rendered by our distributors and of these fifty-two have in their service organizations one or more men with more or less Pierce-Arrow service training who are giving satisfactory service.

Freezing Points of Alcohol-Water Mixtures

THE Air Service, Engineering Division, McCook Field, has worked out a tabulation of freezing points and specific gravity of alcohol and water mixtures which are applicable to automobile as well as airplane practice. A number of tabulations have been gotten up by various individuals and curves printed showing freezing points. It has been noted that marked discrepancies can be found among these various tables and it is of value to have one which has the sanction of the McCook Field laboratory.

As a result of the examination of various anti-freeze solutions by the Air Service, it was found that alcohol-water mixture gave the best results, considering temperatures at which ice crystals would form in solution, running temperature for radiator mixture, ease with which solution can be prepared by the mechanics, and cost of materials involved for producing the mixture.

It should be remembered that mixtures of alcohol and water have a much lower boiling point than water alone. For this reason it is well to keep the water temperature below 167 deg. Fahr. where possible and never allow it to reach 176 deg. for any considerable length of time, as loss of alcohol will take place very rapidly. The following tabulation gives the freezing point of alcohol-water mixtures:

FREEZING POINTS OF ALCOHOL-WATER MIXTURES

Percentage of Alcohol by Volume	Temp. Deg. Cent.	Temp. Deg. Fahr.	Percentage of Alcohol by Volume	Temp. Deg. Cent.	Temp. Deg. Fahr.
0.0	0.0	+ 32.0	25.0	— 11.5	+ 11.3
2.5	— 2.0	+ 28.4	27.5	— 12.9	+ 8.8
5.0	— 2.8	+ 27.0	30.0	— 14.8	+ 5.4
7.5	— 3.2	+ 26.2	32.5	— 16.0	+ 3.2
10.0	— 4.0	+ 24.8	35.0	— 18.3	— 0.9
12.5	— 4.7	+ 23.6	37.5	— 20.0	— 4.0
15.0	— 6.0	+ 21.2	40.0	— 22.1	— 7.8
17.5	— 7.1	+ 19.2	42.5	— 24.0	— 11.2
20.0	— 8.5	+ 16.7	45.0	— 26.9	— 16.4

			50.0	— 31.1	— 24.0

Preventing and Controlling Factory Fires

There are two major phases of factory fire prevention. The one concerns the use of fire resistive materials in the construction of buildings; the other relates to elimination of potential fire centers of one kind and another through the plant. This article discusses both factors.

By C. A. Briggs

SOME thirty or forty years ago when fire resistive buildings of the steel beam type were first erected fear was expressed by some officials of insurance companies that if this new type of "fireproof" building were to become popular, insurance against fire would soon be unnecessary. Since that time there have been innumerable instances of the fallacy of this idea. The fact is often overlooked that while the building itself may be of fire resistive material, there are few buildings which do not contain a sufficient quantity of combustible material to cause a considerable fire.

Some persons, however, still indulge in this false feeling of security, taking it for granted that their lives and goods are safe in what we term to-day fire resistive buildings. But this is not the case. Take as an example the destruction by fire of the Vanderbilt Addition to the Fine Arts Building in New York, with the loss of many priceless paintings, sculptures and other irreplaceable art treasures. This fire occurring the day before the opening of the thirty-fifth annual exhibition of the Architectural League caused architects throughout the country to sustain an almost personal loss.

While these things are distressing, there is reason for hope if through this awakening architects will have brought their professional training and research to bear upon the fallacy of what we used to term "fire proof" buildings. We have learned long since to say "fire resistive," but there are degrees that must be recognized even in the use of this term. Many architects, however, now feel very keenly their responsibility as regards the material they specify in buildings that from the nature of their use should be as far as possible proof against fire. The replies from a questionnaire sent out to a number of architects of schools, hospitals and asylums, however, seem to indicate that any approach to fire resistive or slow burning construction is accepted by some as "fire proof" and that no provision is made for the material that might be housed in these structures.

Regardless of the character of construction, any building that has or may have combustible contents, should have ample provision made for fire protection, usually some standard type of sprinkler system. This conclusion is based upon an exhaustive study, by the National Board of Fire Underwriters, of recent fires in buildings that were supposed to be non-hazardous.

It has been stated before the Structural Engineers Society of Pennsylvania that there is in the ordinary office building 100 ft. wide and 100 ft. deep, twelve stories high, enough fixed combustible material to run the Mauretania 24 hours, which in that time burns 1200 to 1300 tons of coal.

In an excellent article entitled "Steel Furniture and Trim," C. E. Worthington discusses the great value of steel furniture and metal trimmings, which unfortunately have reached a price that makes their general use almost prohibitive. Experiments have proved that steel desks, filing cases, metal waste baskets and other metal office equipment have a high preventive quality. A few years ago metal window frames, sash and casings could be had for very near the cost of wood, and it is to be hoped that this condition will not be long in returning.

FACTS ABOUT FACTORY FIRES

A CLEAN factory seldom burns.
Fire loss is not limited to fire damage.
All fires are preventable, except those due to arson, lightning, and explosion.
It is not only what a building is made of that counts, but also what it is filled with.
All fires begin as small fires.
America's annual fire loss is more than $250,000,000.

The National Fire Protection Association says in one of their recent bulletins, "We must come eventually to the equipment of all commercial, factory and office buildings with metal window frames and wired glass. This will mean the abolition of the conflagration hazard in our cities. Fires will then be unit fires, extinguished easily by a competent fire department within the building in which they originate, for the protection of window openings not only prevents fire from entering but prevents fire from issuing out of the burning building. We may expect an occasional exceedingly hot fire to break down the defense of an adjoining building, but it is obvious that a conflagration could not get under way with fire resistive construction with properly protected window openings."

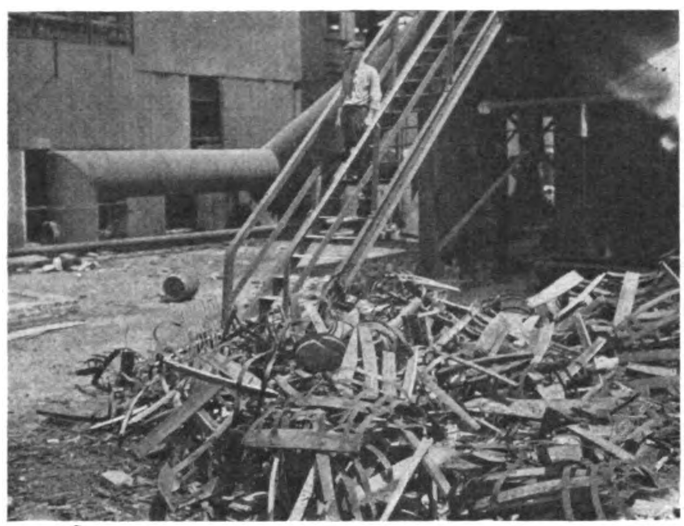
While emphasis is laid heavily upon metal window frames and wired glass, there are other openings in the side walls to be considered. These include such things as ventilators, unused exhaust vent openings or drips. We recently read of the complete gutting of a building that was equipped fully with metal window frames, shutters, etc., because the flames shot through an opening the size of a man's hand from an adjacent burning building.

Whatever the resistive quality of the building, rein-

forcement, consisting of adequate fire fighting apparatus must be provided.

But building material is only one phase of fire protection work. The other important factor relates to those numerous bits of negligence which are usually the cause of fires. The present attitude of public opinion regarding the liability of fires from easily avoidable causes is taking a definite trend. Already the cities of New York, Cleveland and the State of Pennsylvania have laws which provide that any person, firm or corporation on whose premises fire originates because of negligence or failure to comply with any law or ordinance shall pay to the city the full value of the services of the fire department and any damage in person or property resulting thereto in extinguishing or attempting to extinguish such fire. These laws are forerunners of what may be expected in many cities and states in the near future. In other words, the American people are to be made to recognize their responsibility for the elimination of fire causes and the prevention of these enormous unnecessary losses.

The National Board of Fire Underwriters recently announced that property worth $1,416,375,000 was destroyed by fire in the period from 1915 to 1919 as revealed in the quinquennial analysis of 3,500,000 adjustments made by the Fire Underwriters during this five-year period. This loss is the equivalent of 283,275 houses at $5,000 each, or more than enough to shelter the total population of a state the size of Connecticut.



A commonly overlooked fire hazard. Accumulation of rubbish which may easily contain nucleus for a serious fire. In this case it is also a tripping hazard to employees using the stairway

Electricity was given as the chief cause of fire loss with a total for the five years of $84,086,471. Matches and smoking was found to be second with $73,474,348 and defective chimneys came next with $56,650,915. Other causes in their order were: stoves, furnaces, boilers and their pipes, $55,133,181; spontaneous combustion, $49,702,886; lightning, $39,828,489; sparks on roofs, $29,271,585, and petroleum and its products, $25,910,434. Incendiarism contributed $21,596,965 to the damage, and miscellaneous unknown causes completed the total.

By far the greatest proportion of this immense fire loss occurs in industrial and manufacturing property and it would seem that the prevention of fire destruction is not progressing in the same way that other life and property protective measures are doing. If fire hazards were attacked with the same enthusiasm and in the same systematic manner which is now being observed in accident prevention, sanitation, welfare and housing problems, a more favorable report from year to year would appear instead of a steadily upward trend in fire losses. In 1918, moreover, there were 15,000 lives lost in flames in this country.

The illustrations used herein of fire hazards are not exceptional and they doubtless could be duplicated in hundreds of instances.

The automobile industry has definite fire dangers. Every manufacturing establishment has its own peculiar fire hazard. The lumber business, the paint and varnish industry, enameling plants and garages, for instance, all have what might be termed a distinct fire hazard. And the automobile industry in its highly organized state, has in some form, all these fire dangers with which to contend. This makes it advisable, if not imperative, that insofar as possible fire resistive buildings be used and that effective equipment be kept in readiness to fight the fires which are apt to break out where paints, varnish, gasoline and other volatile liquids are handled.

Under these conditions, too, a fine bit of discrimination must be exercised when the flames are approached. If it be an enameling vat or an oil tank that has caught fire, for example, it should not be attacked with a line of hose from a water hydrant. There is also an element of danger in training a stream of water on a blazing motor.

There are certain kinds of chemical extinguishers on the market that must be used with discrimination if they are to be effective. The essential thing is to select equipment suited to the existing hazards, keep the equipment in good condition, in the right place, and under the care of men who are apt to use good judgment in an emergency.

The selection of fire extinguishers is a very important factor and the judgment of experts should be followed. The claims of various concerns manufacturing this material cannot always be relied upon and it is wise to call for aid upon such agencies as the Underwriters Laboratories, Chicago, or the Factory Mutual Laboratories, Boston, either of which can give expert advice as to the proper equipment suited to your case. The selection of fire hose is especially difficult, since it is practically impossible to distinguish between good rubber lined hose and bad, when it is new. Hose bearing the Underwriter's label can always be relied upon as having passed the test required.

The Safe Practices pamphlets which are issued by the National Safety Council, Chicago, contain excellent advice and guidance on practically every phase of the fire problem and they should be consulted for a more detailed study of this subject.

With the help of such concerns within range no manufacturer should find himself unprepared should fire visit his premises. However commendable it may be to prepare to stop fires after they have started, it is vastly more commendable, though less spectacular, to be able also to say, "'My house is in order,' go where you will, in the unfrequented corners of the basement, in the storage loft, look under benches, in dark corners and cupboards and you will not find me negligent. I have removed the evidence and as far as humanly possible I will not be guilty of contributing to the 'national ash pile.'"

A GERMAN syndicate has made an offer to the Brazilian Government to establish automobile, balloon, and agricultural implement factories in the State of Minas Gereas, according to a cablegram to the British Foreign Office from the Brazilian consul in Berlin. Special concessions in duties and freight rates are requested.

Norway Bars Passenger Car Imports

Destruction of roads not built for automobile traffic and depreciation of krone laid to large importations of motor cars. Motor traffic, which is considered a luxury, subjected to rigid regulations. Maximum weight of truck and load is 5 tons. Pneumatics or larger solid tires required.

A. L. FIELD, American representative of Sigurd Gran Rishovd of Christiania, Norway, writes:

"The large importation of motor cars into Norway during the last two years is usually blamed for the falling of the Norwegian krone to about half of its normal value in international exchange.

"The increased use of motor cars and motor trucks on Norwegian roads, which were built for light traffic only, has damaged them so seriously that all the main roads, even those built in the last two years, will have to be entirely reconstructed.

"Motor traffic is considered merely a luxury here, and this, together with old traffic regulations, has discredited the automotive industry with the authorities.

"In an endeavor to improve the exchange, the Norwegian Government has taken the drastic action of restricting the importation of everything they consider a luxury, and the first thing singled out was the passenger car. Norwegian dealers in passenger cars were not permitted to import more cars than they had in transit and paid for, before and on the first of August last. No more passenger cars will be permitted to enter Norway before the rate of exchange has improved considerably.

"Owing to the enormous expense of rebuilding the Norwegian roads, the authorities have found it necessary to regulate traffic to suit the roads instead of building the roads to carry the increased traffic.

"This was done by drawing up new regulations for motor trucks, the Government Road Commissioner being appointed the chairman of committee designated to draw up the necessary regulations. Under them, motor trucks of 1¾ tons load capacity, and less, are not permitted on the roads unless they are equipped with pneumatic tires. The committee, not satisfied with the standard size tires used on American trucks, decided that tires from 1 to 2 in. greater than the standard size would have to be placed on American trucks if they were to be used on the Norwegian roads.

"It is also specified in the regulations that the weight of the truck and the load together must not exceed 5 tons. This practically limits the trucks to 2½ ton sizes or less.

"The accompanying chart is the result of the efforts of the committee appointed to draw up the new regulations for motor trucks."

AN exhibition of agricultural machinery and a series of motor tractor trials are to take place at Lerida, in Spain, from April 1st to 10th next. All kinds of agricultural machinery will be admitted, including machinery used in the derived industries. Manufacturers of fuels, lubricants and all accessories used in connection with agricultural machinery will also be allowed to exhibit. The address of the Organizing Commission is, Urgel, 197, Barcelona.

Norwegian Regulations Regarding Tire Sizes

Effective Jan. 1, 1921

Unless special permission is granted by the Road Commissioner, motor cars are not allowed on country roads with tires below the sizes specified herewith.

Front Wheel					Rear Wheel					The stated axle loads correspond to the following load capacities in tons.
Weight on axle at full load, lb.	Pneumatics		Solids		Weight on axle at full load, lb.	Pneumatic		Solids		
	Inch	mm.	Inch	mm.		Inch	mm.	Inch	mm.	
					2420	Single 4½	Single 120	Not permitted	Not permitted

The FORUM

Hub Standardization

Editor AUTOMOTIVE INDUSTRIES:

This question of Hub Standardization has been given by me much thought and leaves me in a somewhat peculiar position which I think it well to place before the industry through your magazine so that the subject can be ventilated.

From the point of view of the manufacturer, interested in quantity production at a low price, there is no question but that a large measure of standardization should be adopted and put into effect. I feel that the standards at present before discussion will save expense in the manufacture of roller bearings; they may save some slight expense in the manufacture of hubs, and they will certainly save some expense in the manufacture of wheels. At any rate, from the manufacturing standpoint, the existence of standardized hubs will eliminate many troubles which arise and will have an effect of rendering our inventories more liquid and by the reduction of cost may, perhaps, have an effect on the actual merchandising.

The above is a selfish view, based solely on my own desires as a manufacturer. At the same time, however, there is a lurking suspicion in the back of my mind that such standardization may lead eventually to loss of individuality. This is a question which has not yet, however, come up seriously, though looming in the background, and thinking again, as a manufacturer, of the immediate dollar, I am inclined to dismiss it.

It is, however, in my other capacity as an engineer, thinking more in terms of the industry as a whole than of one particular section of it, that I am inclined to question the desirability, or even advisability, of this at this time. I feel that as an engineer, and a member of the S. A. E., I should be asked to take a much broader view of the whole industry rather than a more intimate, selfish view of a small portion of it, namely, wheel makers and makers of axles for sale to assemblers. I feel that if this step be taken that it must, perforce, lead to other steps being taken, with an ultimate deadening of initiative in many other important parts of the car or truck.

Please take the existing standards that surround the front axle, lay out those proposed on a sheet of paper, lay out the center lines for the spring pads, which are practically standardized by virtue of the standardization of the width of the frame, lay out the felloe bands and tires with their position relative to the center of the axle, all of which has been standardized, and you will be surprised to find how little remains to be standardized on the front axle. It is all very well to state that each of these has been standardized irrespective of the other, but if you standardize a series of points, Euclid's law that a straight line is the shortest distance between two points, naturally brings about a standardization of the connections. Therefore, with these points standardized, it is a most elementary proposition to sketch in the balance and have a standardized front axle. There remain, virtually, only the yoke on the steering spindle and the depth of the spring pad from the steering spindle; standard clevises for the steering tie rod practically complete the picture.

The front axle is practically the first thing one sees in the truck or car. Study the advertisements of a number of makes and you will often see them surmounting a hill, evidently showing great power or great speed, with the front axle very prominently displayed. Is it a wise thing to reduce all axles to the same dead level of size and shape? A friend of mine, who has just returned from England, was driving a prominent American car over there and states he was asked repeatedly was his car one or other of a number of makes, and was told that it was very difficult to distinguish American cars because they all look so much alike.

It seems to me that any step that tends to a leveling of design is greatly to be deplored and should be considered very long and very fully before being adopted. In this connection, I would like to add that the time interval between the initiation of this proposed standardization, approximately June, 1920, and the time it was brought up for approval, January, 1921, is altogether too short. It savors too much of politics rather than the mature deliberation of an engineering body.

Again, I confess to a feeling that such a sweeping standardization, which will bring about increased production, must necessarily standardize on the basis of the weakest link in the chain. For example, it is stated in the report that the spindle is of such size that even 1035 steel can be used for emergencies. Nobody in their sane senses would dream of using 1035 steel on the truck front spindle, subjected to such heavy work as it has to withstand, but necessarily a proposed standard must take in a poor quality of steel.

Next in order come the bearings. Here again, the different bearings which are made in quantities have to be considered, and the one of the lowest load carrying capacity, with a reasonably large production, is the one on which the standardization must be based, thus penalizing the much higher grade bearing which, for the same space occupied, has a much higher load carrying capacity. The standardization of bearings by size, rather than capacity, has the effect of lessening the attempts to put in increased value, either of material or workmanship, into a given size. It is then up to the salesman for the bearing to base his selling argument entirely on a question of life, and no other point. He cannot preach economy because by the use of the higher priced bearing, being smaller in size, he is able to save in other materials. This is a point which might be argued on by reason of the fact that a large number of producers want two sources of supply and unconsciously set up a standard in themselves based on the lower quality bearing. This is true for production purposes, but is not true when one considers the best design.

I have a feeling that this bearing standardization by size for certain types of hubs, is actually based on the fact that there has been a failure to standardize sizes of roller bearings in the same logical sequence as exists in ball bearings. Because of this failure to do the thing properly, we are compelled to do this improperly, with possibly detrimental results at a later date to a true standardized logical series of roller bearings.

I am willing to concede, however, that a standardization of taper roller bearings over a limited number of hubs will

bring about more economical results for the manufacturer in the long run. These sizes can be made up in larger quantities and be carried on the shelf with a certainty of disposal, and will tend in many ways to stabilize employment in each factory. It is a truism that the factory having the largest number of customers for a particular object is in the best shape to weather any of the usual industrial depressions and is also in the best shape to stabilize seasonable variations in manufacture.

When it comes to hub standardization, I find myself in grave doubt as to how far this should go. I cannot see that it effects any saving whatsoever. On the contrary, I can see nothing but new expense for dies, for patterns and tools, and an addition to the existing types by a new type. As an engineer, interested in the broad aspects of economy, I would rather have seen the committee pick out a number of existing hubs and standardize on them rather than adopt a completely new line. I feel that if a standard dust washer and standard locking nut are included that it is only a little step more to standardize the complete hub, including the hub cap attachment. Personally, I would, however, rather not see a standardization of these two small parts, not because I feel that the proposed idea is not good and that I know of something better, but simply because on the part of one of them, namely, the dust washer, I feel that we have not reached a final satisfactory design. On the locking device, some factories are tooling up to make one type better than any other and this should be left to stand.

All of the above leads me to a feeling that there is coming a parting of the ways in the S. A. E., for engineers who are concerned with the manufacture of specialized products, or for engineers who are concerned with the industry as a whole. I have not the slightest objection to such standardizations as outlined above, in fact I am in favor of them provided it is distinctly understood that they are for a localized or specialized group of manufacturers. I do feel, however, very strongly that they should not be made a part of the national Society dealing with engineering affairs in a broad way, as such standards are not, and cannot be, true standards in every sense of the word. I would venture to suggest that some other word be adopted to signify such standards as a distinction from what might be called "national" or "fundamental" standards. I do not like the word "standards" at all in this connection; "recommended practices" is slightly better, but again it does not express the facts. For example, how can one say this is a "standard" or even a "recommended practice," when the White Motor Co., admittedly one of the finest truck builders in the country, has a hub totally different from that proposed, and further will in all probability never adopt the one proposed. Similarly, with some other manufacturers who could be named, their probability of adopting the proposed standard is almost nil.

As I said, I do not know what this name should be and have little suggestion to offer. There should be some very strong distinction, and further voting on such proposals should be limited strictly to the groups that will benefit by this work and should not be opened broadcast to the Society. I would suggest, Mr. Editor, that you open up the columns to a discussion on this and to a suggestion of how best this shall be handled. Perhaps a suggestion like this—"axle manufacturers' standard practice," or "wheel makers' approved practice"—might be adopted.

Last on this subject, I would like to add a few words more, although I already feel I have taken up a lot of your space. Many of these standards, or recommended practices, are adopted for the sake of saving the designer some time and allowing him to think of higher things. It is admitted that the most valuable part of this work lies in the committee meetings where the members discuss their own practice very intimately and with great benefit all around. Might I suggest that the S. A. E. gather together many of these engineering practices, just as Professor Unwin used to do in his textbook on Engineering Design, and submit them as part of the work of the Society for consideration. This would lead to a much more intelligent action when the time came for approving the particular practice.

For example, take the case of this hub standardization. It would be in order to have the Society print drawings showing typical Timken hubs, another with typical Eaton hubs; similarly, typical practices of the White company, the Pierce-Arrow company, Packard company, Riker company, etc., could be embodied and these practices would be a distinct guide to a draftsman or designer in arriving at his own conclusions. There is no use disguising the fact that every one of us, when redesigning some part of his car or truck, takes out his yardstick and goes down and measures the other fellow's work. The S. A. E. would be doing a wonderful thing in collecting a lot of this information, publishing it, and eventually, providing the tendency were shown, they could collect this, boil it down, and adopt an approved practice. This practice should be based on what is best, and not on what is average. As I have pointed out several times, the average is just as near to the bad as it is far from the good.

An afterthought occurs to me. Why should not the hub cap be standardized inasmuch as this would lead to a considerable economy in manufacture by the hub odometer people? Please note in asking this question I am not suggesting it is advisable to do it, or desirable, but am simply asking a question that seems to be just as logical as others.

JOHN YOUNGER.

THAT certain kinds of research work having to do with specialized industry cannot be carried out advantageously at universities, but should be entrusted to the research associations which are able to concentrate on particular problems is the contention of F. W. Burstall, Professor of Mechanical Engineering at Birmingham University. At this university the study of the internal combustion engine is being attempted on lines somewhat different from those which have been in vogue previously. Professor Burstall wants to obtain results as to the behavior of internal combustion engines which shall be independent of any particular type of engine or kind of fuel. For this purpose he has constructed an engine in what he terms a theoretic form to show all the changes of temperature which take place in the working fluid.

A small motorcycle used in Switzerland. The weight is said to be but 32 lb., the speed 15 m.p.h.

Number of Working Hours as Related to Production Cost and Rate

The factor of mental fatigue enters into the question of working hours as well as that of physical fatigue. The relation of working hours to unit production costs was brought out in a letter from an automotive manufacturer, which is quoted and discussed here by Mr. Tipper.

By Harry Tipper

FROM one of the subscribers of AUTOMOTIVE INDUSTRIES I have received a letter concerning the relation between hours, production efficiency and fatigue which is of unusual interest, and for this reason I am quoting liberally from the letter as follows:

In one of the plants employing approximately 3000, working hours were reduced from ten to nine, piece work prices remaining the same per piece, under the new schedule as obtained before and hourly rates increased the necessary percentage so that a man's labor for nine hours paid him the same as had been paid for ten previously. The actual net result of this move was to slightly decrease actual cost of production per unit.

In the other plant, employing approximately 600 men, time was reduced from ten and one-half to nine and one-half hours per day. There was practically no piece work in existence. Hourly rates were increased so that a man's earning capacity in nine and one-half hours at least equalled and in some instances, so as to avoid splitting a cent for an hour, a man's earnings were better in nine and one-half than had previously been obtained in ten and one-half. And in comparing the costs per unit of production between 1916 and 1919, during which time the original hourly average rate had been increased about 75 per cent, the actual cost of production per unit in 1919 was about one-half of 1 per cent less than in 1916.

The move, of course, was not made with the primary idea of reducing costs below the pre-war costs, but the move was made, however, on account of knowledge gained in the former experiment with 3000 men and it worked out to extremely good advantage with the crew of 600.

This company is not reducing hourly rates. We are, however, shading selling prices and it is being done by slight reductions in costs of both material and labor. The labor reduction is being accomplished by letting the individuals who actually do the work, realize the fact that the management of this institution does not pretend to believe that the mentality or brains of the institution are contained in one particular cranium.

Apropos to the long hours, fatigue, etc., I have had during the past eight or ten years a good many conversations with rather high class employees, although they were plain workmen, not officials in any capacity, of some of the big, high speed, intensively advertised manufacturing plants and it seemed safe to conclude from these conversations that absolutely the only reason why men stayed with them was because of the money that there was in it. They confessed though, that at the speed at which they were driven and at the hours that they were forced to put in, they dreaded daily, going to the place, as virtually they were more tired on arrival at the shop in the morning than they were after they got into action. Furthermore, these particular men seemed to find it necessary to take time off semi-occasionally to recuperate.

These instances are not unusual in their indication that the number of hours worked does not have a very close relation to the production rate and that the operation of a ten-hour day may not be economical even though the pay is based upon a day's labor and not upon an hourly payment.

There are many other instances where the reduction in the working period has led to an increase in the efficiency, so that the earnings of the worker could be maintained or even enlarged while the labor cost per unit has decreased.

The question of hours is necessarily bound up with the question of fatigue and the last paragraph of the quotation is interesting because it affords the reason for the effect secured in the instances indicated in the earlier paragraphs. High speed, concentrated work on repetitive operations is fatiguing in the extreme and the effect of the repetition of similar motions on the nerves and muscles has been known for a considerable time to the medical profession. Not so much is known of the mental fatigue which results from this type of work, and the effect which that mental fatigue has upon the actual physical condition.

It is not economically sound to arrange the working periods so that there is an accumulated fatigue which cannot be overcome in the periods of relaxation. Not only is this the case, but the effect of the fatigue from concentrated work is to demand a type of relaxation that is not really a relaxation at all, but simply changes the character of the mental pressure.

The strained concentrated character of the repetitive work in the needle trades, directly demands the activity of the dance, the emotion of the melodrama and the mental stimulation of sentimental excitement as a relief from the narrow concentration of its efforts. In a much more definite form it demands the relief which induces the schoolboy (on his release from the class room) to indulge in fight, noise and all the physical activity which he can secure. In the older persons the demand is more sophisticated and relieves itself through the channels which I have mentioned.

At the first glance this sounds as though it had very little to do with the working efficiency, but the accumulated fatigue results in the establishment of a minimum pace that is only increased under pressure of economic fear. It results also in a degeneration which was definitely observed by medical students in Great Britain before the war, and which lead to a complete revision of the army tests in that country.

Unforunately, the knowledge which we have gathered medically has not been applied industrially so that we could determine the most economic period for the working hour under various conditions of operation. We are still misled into thinking that because a man works ten hours, he does more than he could in nine hours.

We are still under the impression that the hour's work is subject to a definite limitation, and that we lose the production effect because the working period is shortened. This persists, despite the fact that many careful observations have been made, indicating the production curve average under different conditions and drawing some conclusions from these examinations as to the relation between production, fatigue and work. These observations, however, did not go far enough, as they do not take into account the part which is played by the mental fatigue arising out of the destruction of the incentive and the elimination of interest in the work. These factors affect the production capacity to a great degree and they influence the accumulation of fatigue to an extent which has not been admitted.

This question has no relation to the demand of the labor union for shorter hours, and it is not affected in the least by the circumstances of that demand. It is a matter of arriving at the working period which will produce a maximum production and therefore the minimum cost per unit produced.

It calls for a consideration of labor cost in its definite relation to the production effect, and it requires a careful study of the work, the concentration and repetition demanded by the work, the reaction upon the man and the fatigue induced by the continuance of that reaction over a definite period. It is an intensely practical way in which to study the human relations in the plant with the possibility of a great practical benefit on both sides.

This is the kind of study which must be given to the human question if we are to be thoroughly informed thereon and thoroughly efficient in our consideration of it.

There is no possibility at the present time of determining with reasonable accuracy the working period which is of the greatest advantage in connection with definite lines of work or definite industrial occupations.

We operate blindly on eight, nine, ten or twelve hours, according to custom and tradition, and without any knowledge of the advantage or disadvantage accruing from this method. As a rule, we are not even patient with the man who desires to investigate such matters and are inclined to dub him impractical, or suspect him of sympathy with the workers to the detriment of the employer.

Sooner or later, however, we shall be forced to consider the question and to consider it with proper investigation and study. It will pay us to consider it, because we can only work at the greatest production efficiency when the worker is operating with the least fatigue and with the quickest recuperation.

Opportunities for Dealers Visualized in Exhibit

SOMETHING unique in the line of factory sales extension effort was introduced by the Nordyke & Marmon Co. during the New York show and is scheduled to become an important feature of the Marmon exhibits in several of the season's larger shows.

It is known as the "Dealer Opportunities Exhibit" and is designed primarily to attract the attention of desirable dealers and sell them the Marmon idea. The exhibit comprises a series of screens upon which are mounted specimens of the various sales extension activities of the factory sales organization and presenting a detailed outline of what the factory is doing to assist its dealers in merchandising its products.

While it is expected that the exhibit will interest many dealers and influence them in the desirability of the Marmon contract and its promise of real merchandising assistance, it is not the plan of the Nordyke & Marmon sales department to depend entirely upon the exhibit to make the contact with these individual dealers at the shows. The exhibit is, rather, a closing room, where dealers that are desirable through territorial location or for other reasons, may be brought by Marmon distibuters for a detailed exposition of the Marmon merchandising plan—where the closing effort in the sale of a Marmon dealer contract is made.

Within a few days after the exhibit was opened in New York factory representatives in attendance noted not only the fact that it was selling Marmon to the dealers who were casual visitors, but it was selling existing Marmon dealers on the advantages of their contracts.

The exhibit shows how the factory sales organization is prepared to assist in the merchandise of Nordyke & Marmon products through its advertising, sales letter, sales and service instruction, territorial analization and other activities in the interest of its dealers.

To some of the Marmon dealers it proved a revelation for, while they were more or less familiar with the things the factory was doing toward sales stimulation, many of them realized for the first time that they were not availing themselves fully of the opportunities that were within their reach and they left strongly sold.

One of the features of the exhibit that was particularly interesting to visiting dealers was the Marmon plan of territorial analization. In this section maps showing graphically the distribution of population, property valuations, car registration, wealth distribution and road conditions in specific dealer territories were shown. The factory sales extension department is preparing to extend this service to all of its dealers on request.

AN Alloys Research Association is being formed with an Alloys Information Service as the first step. This is to be co-operative on the part of those interested in metals and their alloys. An advisory committee, composed of 17 prominent technical men, was formed some time ago and this committee has evolved a plan, in conference with the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers, whereby a service of a different scope from any now existing can be carried on for the benefit of the alloy men. The Research Extension Division of the National Research Council, Washington, D. C., which is aiding in the organization, will be glad to supply fuller details about this service.

Better Brakes Needed

BRITISH and other critics of American cars say with more or less justice that the design and construction of the brakes fitted on our cars do not compare favorably with the practice common abroad or even with the practice with respect to other parts of our cars. This criticism does not, of course, apply to all American cars, but it is true in general that careless design and faulty workmanship is more common in connection with brakes than with any other important part of the car.

Brake drums frequently run out of true, and the band brake so frequently used on the rear wheels almost never bears evenly and usually drags at one or more points. It is true, as one of our correspondents has pointed out, that the band brake is easily adjusted, and can be readily taken off and relined without removing the wheel, but these aside from light weight seem to be about the only points in its favor, at least so far as its use on the rear wheel drums is concerned. On the other hand, it catches dirt, frequently squeaks or rattles and is, in short, too unmechanical to find a place on a well-designed car.

More study of brake lining materials should result in some betterment in construction, and methods of testing linings now being investigated at the Bureau of Standards should be helpful in this direction. There is much to be said also in favor of the use of transmission brakes, and, on the higher grade cars, of front wheel brakes.

Beyond question there is much room for improvement in braking systems as applied to the average American car. The subject is deserving of more study, and should not be overlooked at this time when the wise and progressive car manufacturer is seizing every opportunity to improve his product.

A Basis for Tax Revision

IT is curious that frequently some person will reduce a seemingly complicated problem to a primary analysis and will be hailed as accomplishing a great work. A recent example of this sort of reasoning and its effect is the Federal tax platform as issued by the National Automobile Chamber of Commerce.

It occurred to some one on the N. A. C. C. tax committee that the drafting and application of a tax program was a technical problem and that the average automotive manufacturer had no more reason for attempting to solve it than he would of going into his engineering department and laying down the details of the design of a vehicle he proposed to manufacture. Rather the manufacturer and the board of directors would generally outline the vehicle, provide the funds to employ the proper technical staff and say to the chief engineer, "We want results."

This theory was applied to the tax situation. The men on this tax committee reverted to the almost forgotten theory of democratic government that it is "of the people, by the people, for the people." In other words, the people should and must inform the technicians in charge of governmental work how much they shall have to spend on this work, just as the stockholders, speaking through the directors, tell the factory administrators how much money they can have for the coming period of activity.

As a part of this platform, the N. A. C. C. declaration holds that this generation, which has borne the direct injury of the war, should not be required to pay the entire bill of costs—that this cost should be refunded to spread the cost over at least two generations. This is the first proposal tending toward a decision as to how much should be levied in taxation.

As a second proposition, it is suggested that an analysis of governmental appropriations be made with a view of finding where economy can best be made. It is taken as a truth that the new administration is quite willing to carry into effect its pledges for a business and economical administration. Then it remains only for the people, through their spokesmen, to point out wherein they want economy enforced. It is believed that it is reasonable that representatives of business and civic and industrial organizations can speak for the people.

This platform of the N. A. C. C. has been widely distributed and the committee is receiving many let-

ters of praise, a number of which employ superlatives in recommending this plan.

The plan, as printed, points out forcibly that class taxes are objected too, that especially is it the view that excessive profit and surtaxes are not considered wise. Also that a sales tax does not seem desirable. But these points are not the major ones. The committee will submit that IF a sales tax is necessary, and that IF other objectionable taxes are necessary, that the method of employing them for the raising of the necessary money for the government should be decided by tax experts with a view of even justice.

It is interesting to note that the N. A. C. C. has not asked any association or person to adopt its tax platform, but that the committee has only asked if the principles set forth are common. It is much preferred that other associations use the principles in their own way. The committee has learned that it is not entirely a pioneer in this method of attacking the problem. A similar tax plan was drafted some weeks ago by the Rubber Association of America, but was not given publicity.

There is evidence that, with the technicalities dropped, there will be a nearer approach to agreement on a common tax platform.

Unemployment Responsibility

THE problem of unemployment, though never so acute in this country as in England, is important enough to merit serious consideration. A fundamental question for discussion in this regard is that of responsibility. Does the world owe a living to every man able and willing to work? If so, upon what group or agencies rests the responsibility for providing profitable employment or at least subsistence in times of unemployment?

In England the government, the trade unions and a few employers are assuming a part of that responsibility. There it is a matter of pressing need; some action is necessary immediately, whether fundamental lines of action have been determined or not. The article by C. H. Northcott in a recent issue of AUTOMOTIVE INDUSTRIES discusses the British situation.

Under an industrial organization such as we have to-day with the power of employment and unemployment in the hands of employers, it would seem that a considerable part of the responsibility must rest upon that group. Industrial depressions which take away from many men the opportunity to earn a living are, in a certain sense, an indictment of our industrial organization.

Even in this country conditions become so acute as regards unemployment at times that some immediate remedial measures are necessary. As Henry S. Dennison remarked recently in connection with the unemployment benefit plan being worked out at his plant, "There is a very definite need present right now; something needs to be done. It doesn't do to be too academic about the proposition at such a time. We are trying to work out a practical scheme at our plant to meet present conditions. We think we are on the right track."

And in the meantime, this question of the final resting place of social responsibility under our present industrial system should be carefully thought about by every industrial executive. Some general agreement having been arrived at on this score, the next step involves practical means for putting into action the principles conceived.

Fuel Economy Comparisons

WHAT low fuel economy we are getting in kerosene burning tractors is well brought out by the results of the Nebraska tests circulated at the Columbus show. In stationary gasoline engine practice it has long been the rule to figure on a consumption of one gallon per 10-hour day per horsepower, which is equivalent to 10 horsepower hours per gallon. Considerably better results are possible under specially favorable conditions. For instance, tests made on a 185 hp. B.M.W. aircraft engine at McCook Field showed a fuel consumption of only 0.42 lb. per horsepower hour. As the gallon of gasoline weighs about 5.75 lb., this corresponds to 13.7 horsepower hours per gallon. This, according to the Air Service, is the best figure ever attained in its tests and may be regarded as the practical limit for the present.

By way of contrast it is interesting to note that one of the tractors tested at Lincoln developed only 2.45 horsepower hours per gallon of fuel and the average of all sixty-five tractors tested was only 4.5 horsepower hours per gallon. This average would be even lower if the few tractors burning gasoline had been disregarded, as these on the whole consumed relatively less fuel than the kerosene tractors.

There is just as much energy in a gallon of kerosene as there is in a gallon of aviation gasoline; slightly more, in fact. That the fuel economy of tractors is only about 50 per cent that of fairly large stationary gasoline engines is due chiefly to two causes, as follows: (1) Low compression must be used with the kerosene to prevent knocking, and (2) a good deal of the kerosene either passes through the engine unburned or else burns so late in the power stroke that practically none of the heat of combustion can be turned into useful work.

It may seem unfair to make a comparison between the fuel economy of a tractor engine burning kerosene and a large size aircraft engine burning a special grade of gasoline, as there is very little chance of attaining the economy of the latter with the former. A more useful comparison is obtained if we confine ourselves to apparatus using the same grade of fuel and working under similar conditions. In this connection it is of interest to note that the best performance from a fuel economy standpoint in the Nebraska tests was 6.57 horsepower hours per gallon, as compared with a low figure of 2.45 h.p.h. These consumption figures were obtained while the tractors were on an endurance run in which it was important that they should maintain their rated output. It is not at all unlikely that in some cases the poor economy is due to difficulty in maintaining the rated power, fuel being used in excess to increase the output, but it is doubtful if higher economy would be obtained in regular service.

Industry Looks for Steady Gains

MELLON NOT COMMITTED ON TAX PROGRAM; IMPORTANT CONFERENCES SET FOR THIS WEEK

WASHINGTON, March 7.—Secretary of the Treasury Mellon to-day advised AUTOMOTIVE INDUSTRIES that he had not formed definite plans as to tax recommendations. The secretary stated that he would give this subject thorough consideration and undoubtedly map out a tax program for submission to Senate and House Committees early in April. He has not committed himself to proposed revisions though it is known that as a banker he held very decided opinions concerning the need of abolishing the excess profits tax and providing more equitable substitutes. Before taking office he intimated he favored a corporation tax and a small retail sales tax.

It is understood that the secretary will confer with President Harding this week in an effort to obtain his views on this vital matter. Chairman Fordney of the House Ways and Means Committee, Senator Penrose, chairman of the Senate Finance Committee, and other congressional leaders directing fiscal legislation, have been summoned for conferences with the chief executive. These conferences will have an important bearing on hearings which are scheduled for early April.

The Senate committee on appropriations reported that the last Congress reduced the total appropriations by nearly $1,500,000,000 from official estimates for expenditures during 1922 and approximately $900,000,000 less than total expenditures for 1921. These reductions would indicate a lower tax rate but many bills have been vetoed and may be reintroduced with larger amounts, so that actual expenditures authorized will be difficult to determine for several weeks.

Optimism Reigns at N.A.C.C. Meeting

Shows Break Depression—Farmer Buying Weak — To Push Safety Campaign

NEW YORK, March 5 — Sane optimism pervaded the members' meetings of the National Automobile Chamber of Commerce here this week. The spirit manifested was in marked contrast with that which has been apparent for the past few months. The manufacturers are convinced that the tide of business depression has turned and that the trend of trade will be steadily upward from now on.

While the manufacturers were confident that the readjustment of the industry to post war needs has progressed well beyond the turning point, they do not expect a record-breaking business in 1921 but they do believe that sales will exceed the fondest hopes they dared express two months ago. At that time they were hopeful, but not sanguine, that the shows would bring a resumption of buying. Now they are convinced that the annual expositions have done more than they ever did before for the industry.

There was a perfectly frank discussion of the situation among both passenger car and truck manufacturers. The situation in the passenger car field is undeniably better than in the commercial vehicle end of the business but the market for trucks is strengthening.

Business has not gone ahead by bounds but the expansion has been steady although slow. The belief is almost unanimous that it will continue and that the volume of orders which has been coming to factories the past few weeks has not been a mere flash in the pan.

South Weakest Trade Point

Reports gathered from 20 distribution centers by the National Automobile Dealers Association were read to the manufacturers. They showed a decided upward turn in sales everywhere except in the south and in South Dakota. They have risen to 75 per cent of normal in some districts. There has been a marked increase in sales of used cars but they have been made at much reduced prices. This opens the way for sales of new vehicles.

The improvement in business has come chiefly in the larger cities and trade still is dull in the smaller cities and in the rural districts. Two factors are largely responsible for this condition. One is the fact that the purchasing power of the farmers has been largely reduced and the other is that the credit situation in the rural sections still is unsatisfactory. The resources of small town banks are mostly tied up in frozen loans and many of them have borrowed as much as they can from the Federal Reserve or from the larger banks with which they have connections. Credit conditions in the larger cities are no worse and in some places are better.

One of the chief obstacles in the way of sales in the truck field is that the railroads now have more idle cars on their lines than they have had in ten years. This number is now approaching half a million. The falling off in freight has been the direct result of business depression and has limited the market for trucks.

Ex-Governor Smith Talks Trucks

The truck manufacturers were addressed by Alfred E. Smith, former Governor of New York, who is now chairman of the board of the U. S. Trucking Corp. in this city, the largest company of its kind in the country. He pointed out that storage facilities for trucks are entirely inadequate and that if they were enlarged there would be a much better potential market. His own company leaves in the street each night, 2000 horsedrawn vehicles but it must find roofs to shelter its trucks. There are almost no storage facilities in lower New York.

Both passenger car and truck makers were addressed by John Moody, president of Moody's Investors Service, who discussed "business and financial conditions and how they affect the automobile industry." He emphasized strongly his belief that 1921 would be a year of adjustment for the industry. He declared that no one industry can stand out against lower prices and asserted that even the cost of steel must go down.

While in New York, the manufacturers discussed informally among themselves means they are employing to assist the small down dealer in promoting sales. Several companies are giving these dealers advice and assistance not only in salesmanship, but on finance.

A decided stimulus to the work of accident prevention is expected to follow the appropriation by the directors of $5000 for prizes to school children of the United States for the best essays on how to lessen the number of automobile fatalities. The plan for offering these prizes has not yet been worked out in detail and other agencies engaged in the same work will be consulted before the regulations covering the contest are announced.

Should Check Accidents

The N. A. C. C. directors feel that it is distinctly up to the automotive industry to help prevent accidents. They are much concerned over the situation and believe many of the fatalities are due to the overloading of trucks, the lack of playgrounds for children and reckless driving. While 78 per cent of the automobile accidents are due to the carelessness of pedestrians themselves, the frequency which such accidents are occurring, is injuring the industry.

The N. A. C. C. does not believe the examination of drivers will do any good,

(*Continued on page* 578)

Klingensmith Joins Gray Motors

To Work with Beall on New Light Car

Will Start Production in Summer —Company Has Strong Financial Backing

DETROIT, March 8—F. L. Klingensmith, former general manager of the Ford Motor Co., set at rest rumors as to his future plans by the announcement to-day that he would associate himself with F. F. Beall, former vice-president in charge of manufacturing of the Packard Motor Car Co., in the production of a new 4-cylinder car to retail at around $1500. Associated with Klingensmith and Beall will be W. A. Blackburn, former factory manager of the Cadillac Motor Car Co. who will occupy the same position with the new concern.

The new company will be known as the Gray Motor Corp. and is a reorganization of Gray Motor Co. which has a large plant at Mack Avenue and Terminal Railroad where the company has been manufacturing engines for several years.

Beall joined Gray Motors upon his resignation from the Packard Co. last summer and has developed a high grade engine which has proved a success. The corporation is well equipped for the manufacture of engines in large quantities for commercial use in addition to its own car requirements.

The car will be brought out in the summer. It will have a 112-inch wheelbase, 3½x5 engine and unusual body lines. The success of Beall at the Packard plant assures the highest grade workmanship on the new product. The car will be marketed through 10 distributing centers, each with an assembly plant, and cars will be shipped from Detroit unassembled, reducing sales expense and freight and it is contemplated by this policy to sell the car at the same price in every city. The same arrangement will be carried out in foreign fields.

Directors Name Officers

At a meeting to-day of directors of the new corporation, Klingensmith was named president; Beall, vice-president and general manager; G. H. Kirchner, president of the First State Bank of Detroit, treasurer and J. B. Moran, secretary and assistant treasurer. Klingensmith was with the Ford company for 15 years and the last six years as vice-president and treasurer. He resigned Jan. 1. Since that time there has been much speculation as to his future and the announcement of a combination with Beall is pleasing to his friends.

Klingensmith's long experience with Ford in financing and sales, Beall's mechanical and production experience and the financial backing of men prominent in money circles, are believed to assure the development of another large automobile company in Detroit. In a statement to-day Klingensmith said:

"I consider myself especially fortunate in being able to form a partnership with Beall in view of his splendid training and long experience in quantity production of high grade automobiles. He received his early training in bicycle manufacturing and later spent 12 years with Brown & Sharpe at Providence, R. I., became an official and left the company to join the Packard organization. I consider Beall the best qualified man in the automobile industry to-day from manufacturing, designing and metallurgical experience to develop a new car." The car will be known as the Gray and, equipped as it will be, is expected rapidly to take rank with popular-priced cars now in the market.

SHORT MONTH HINDERS NEW FRANKLIN RECORD

SYRACUSE, March 7—The extra working day in February, 1920, was the only thing which kept the H. H. Franklin Mfg. Co. from setting a new February production record this year.

Shipments for the month totalled 952, thirty-five less than was turned out in the leap year February. The factory was on a 40 car a day schedule which would have carried it over the top by five.

During February the total number of orders received aggregated 1107, the output falling 155 short of meeting demand. Only 850 cars had been scheduled for the month's output but this was increased when the heavy flow of orders became apparent.

The March schedule calls for production of 1031 cars.

Firestone to Decide on Production Policy

AKRON, March 7—Directors of the Firestone Tire & Rubber Co. will meet March 11 to act on the quarterly dividend payment due this month, and also to make definite decision as to the extent of contemplated increase in production. Although Firestone is not contemplating employing any more men for the time being, it is understood that the company plans an appreciable production increase early in April, and expects to follow it with a s'ill greater increase about the first of May.

Economy Forces Out Overland Officers

Assistants Take Over High Positions—Think Production Near —Contracts Changed

TOLEDO, March 7—The policy of enforced economy in the Willys-Overland Automobile Co. here was emphasized again this week when President John N. Willys, here for three days, announced the severing of relations of Treasurer Frank K. Dolbeer with the company. Dolbeer will be succeeded by his assistant, J. H. Gerkens, in handling the finances of the company.

Dolbeer has been associated with Willys for many years. It was while John N. Willys was operating a bicycle repair shop at Elmira, N. Y., and selling talking machines on the side that their friendship began. Dolbeer was "on the road" for a phonograph company. When Willys began to build up his organization here he summoned Dolbeer for one of the big tasks.

The company has not made any announcement of its production plans. The number of cars on hand is down to the very minimum now and production is expected on a small scale most any time. A few Willys-Knight fours are being built now—most of them directly on order of the dealers.

Willys held several conferences with Walter P. Chrysler, the executive vice-president, and Charles B. Wilson, vice-president in charge of the Toledo plant. The policy adopted in regard to economy and building up a new organization has been carried out in disposing of several contracts this week.

The advertising contract, which has been held by the Martin V. Kelly Co. since the beginning of the company's operations here and which is one of the largest contracts of its kind in the world, has been turned over to another firm.

It is understood by Toledo bankers that the bankers' creditors' committee has practically forced President Willys to give over control of the plant to Chrysler, with full power to weed out all unnecessary individuals.

At the present time there are only one or two of the old family of officials left at the Toledo plant. Most of the places made vacant have been taken over by assistants, come up through the ranks.

HENRY FORD D. T. I. PRESIDENT

DETROIT, March 7—Henry Ford has been elected president of the Detroit, Toledo & Ironton Railroad to succeed Joseph A. Gordon. Several other changes were made.

U. S. Army Trucks Sadly Depreciated

Stocks Left in France Allowed to Go to Ruin Through Lack of Care, Reports Show

Complete official inventories of American army supplies sold to France show that on Nov. 1, 1920, their value was 2,066,800,000 francs or $413,360,000 at the normal rate of exchange. Motor vehicles and automotive supplies represented 326,800,000 francs or $65,360,000. It is understood that an effort will be made to reimport to the United States, duty free, an enormous quantity of these stocks, not only automobiles but other goods.

PARIS, Feb. 18 (*Special Correspondence*)—All American Army stocks in France are expected to be liquidated by the end of next July, according to a statement made before the French parliament. Two of the biggest American automobile camps have been disposed of. They are the Pruniers camp, near Romorantin, which has been sold to the Parrot Company for 35 million francs and the Bourg camp, near Langres, sold to the Meynil & Souchal Company for 25 million francs. The M. T. C. repair park at Verneuil, which was the biggest single organization of the Motor Transport Corps in France, has not yet been sold.

Emmanuel Brousse, in a long speech before the French House of Representatives, has given close details of the manner in which the American stocks were received by the French and disposed of by them. For more than a year Brousse was in charge of the liquidation of stocks, and although his speech was a justification of the work he did, he did not hesitate to point out the gross mismanagement and the scandals connected with this organization.

Stock Sold for $400,000,000

The American stocks were purchased in July, 1919, for 400 million dollars, at a time when the dollar was worth about 7 francs, but owing to carelessness or neglect the value of the dollar was not fixed when these negotiations were concluded, so that the French Government does not know how much it will have to pay for the material received. Wholesale robbery of the American camps began before the American army left France, and was continued on even a bigger scale when the troops had gone home. While the American Army had 100,000 men to police their forty parks, the French had only 1500 troops. The Quartermaster Corps depot at Gievres, guarded by 18,000 American troops, was entrusted to 800 French soldiers.

An American captain, according to Brousse, stole 1500 Cadillacs from the Montoir camp, in addition to thousands of tons of goods, sufficient to load two steamers, which were sent from St. Nazaire to America. The captain was sentenced to one year's imprisonment by the Poitiers court.

The camps were generally so difficult to reach, and the vehicles were generally so deeply bogged that all but a few professional speculators declined to attempt to reach them. Brousse inaugurated the system of selling complete camps, in contra-distinction to the earlier method of disposing of single vehicles or small groups. The results in the case of the Bourg and Romorantin parks were marvelous. An expert's report on the automobile camp at Bourg in which the M T. C. left 9000 automobiles, states under date of July, 1920, that this camp, which is four miles from the town of Langres, is on clay ground of such a nature that the slightest rain makes all work impossible.

From the end of September it is practically impossible to operate this camp, and if the material is allowed to remain there until the end of December, 70 to 80 per cent depreciation will have to be allowed for. In winter it is very common for this country to be covered with more than 3 feet of snow.

Important Repairs Needed

At least 50 per cent of the automobiles are in a very bad mechanical condition by reason of their exposure to the elements and the long time they have remained in the mud. Not a single vehicle can be considered in new condition, and all of them need very important repairs before they can be used. Many of the aluminum crankcases have been attacked by the acids contained in the soil. Quantities of frame members are warped by reason of the trucks bedding in the mud. There are no facilities for repairs, much of the material is standing out in the open, and the sheds are in such poor condition that they cannot last through the winter.

No inventories existed when the stocks were taken over. Nobody knew what was in the camps, nobody knew where material was to be found. The American Army declared it left behind 65,000 automobiles, while the French estimate that they did not receive more than 40,000. There were 200,000 boxes of automobile spare parts which had not been opened when the French took charge of the stocks, and nobody knew exactly what these boxes contained.

SLOUGH TRUCK SALE POOR

LOS ANGELES, March 8—Indications are that the sales of American army trucks reimported into this country from England by the Slough Trading Co. have undergone a bad slump. When the sales began the representative here of the British company did a good business, but trade soon fell off and more than half the consignment of 75 is still on hand. There is very little mention heard now of these army trucks.

Pocket Veto Kills Truck Dumping Bill

Much Legislation Unfinished as Congress Ends Session—Economies Affect Industry

WASHINGTON, March 7—President Wilson's pocket veto of the Army appropriation bill put an end to legislation designed to sell or transfer surplus army trucks and automobiles. The Senate and House had passed the bill as received from conference in which the House conferees had prevailed upon the Senate managers to an amendment requiring the sale of not less than one-half the surplus trucks and cars.

The conferees could not agree as to appropriations for the Air Service which the Senate insisted should be adequate. The Senate failed to reach a vote on the Naval appropriations bills and as a result the item for purchase of aircraft equipment will be carried over into the extraordinary session. The Senate amendments concerning the disposition of tractors as carried in the Fortifications bill were accepted by the House and the measure received the approval of the President before his retirement from office.

Under the terms of this bill, the War Department is authorized and directed to transfer 1250 tractors to the Bureau of Good Roads for distribution to the States for use on highways. Senate leaders and War Department officials predicted that the transfer will put the Army on the market for new tractors within a year.

The adjournment of the Sixty-sixth Congress left many pressing bills on the calendar for reintroduction at the present session. One of the notable features of the past session was the failure of the Senate to approve the continuation of the Federal aid appropriations. At the time of the rejection of State aid program it was indicated that the plan of national highways indorsed by the automotive industry would be given consideration at this session.

Defense Council Cut Off

The policy of economy pursued by the House and Senate affected many Governmental organizations in which the automotive industry had a direct interest. The Congress failed to provide funds for the maintenance of the Council of National Defense, which had under way several studies in standardization and highway transport. It is stated, however, that pressure will be brought to bear on the Sixty-seventh Congress for a special appropriation that the work may continue.

Recommendations of the Secretary of Commerce for the extension of the research activities of the Bureau of Standards into problems relating to the automotive industry were ignored by the House and Senate and, as a result, the activities of the Federal scientists will be restricted.

Associations Near Unity on Tax Views

N. A. C. C. and Rubber Association Committees Reach Agreement—Sales Tax Favored

NEW YORK, March 7—Considerable progress has been made the past two weeks in the direction of concerted action by all branches of the automotive industry on the question of Federal taxation. It is confidently believed that before hearings are begun by the House Ways and Means Committee at the extra session, the various organizations representing the industry will have united upon a definite program.

A working agreement already has been reached between the tax committees of the National Automobile Chamber of Commerce and the Rubber Association of America. The committees of the two organizations presented to their directors reports which were practically identical. Both called for economy in governmental affairs, especially in relation to the military establishment, for the funding of the war debt and for a sales tax to provide whatever additional revenue is necessary.

Directors of the National Automobile Dealers Association have decided to stand with the N. A. C. C. on the tax question. A similar position will be taken by the American Automobile Association, and the Trailer Manufacturers Association is expected to fall in line. The Motor and Accessory Manufacturers Association has not yet appointed a tax committee, but it has been committed informally to some form of sales tax, and it is hoped that its views will be adjusted to those of the other organizations.

The tax committees of the N. A. C. C. and the Rubber Association have begun energetically the work of gathering statistics and data regarding the views of other associations on the tax question and will strive to convert as many as possible to their views. As a matter of fact, considerable progress already has been made in this direction. The sentiment in favor of a sales tax instead of increased excise taxes upon industries which have been classed unofficially but arbitrarily as luxuries is growing, in spite of the recent referendum of the United States Chamber of Commerce.

Sales Tax Easy to Collect

The general belief is that a tax on retail sales will be more easily collected than a turnover tax. Estimates show that it would yield all the revenue necessary and that it would impose only about one-quarter as heavy a burden on the ultimate consumer as a turnover tax.

C. C. Hanch, chairman of the N. A. C. C. tax committee, will spend the next few days in Washington investigating the tax situation. No attempt will be made to obtain the views of legislative leaders until the extra session begins. The House leaders themselves, who will initiate the tax legislation, are not united upon any plan. The chief objection to a sales tax is that it would fall directly upon the ultimate consumer whose vote might be influenced by the feeling that he has been discriminated against. Economists agree, however, that this form of tax is the most equitable which can be imposed, and efforts will be made to show consumers that they will pay the taxes, no matter what form they may take.

Representatives of the various organizations connected with the industry are expected to meet frequently for a discussion of the tax program. While it is believed they will unite upon a plan, it is probable each branch of the industry will ask for a separate hearing at Washington rather than make an appearance as a united industry with a single spokesman.

Raw Material Prices Retard Normal Return

WASHINGTON, March 5—Nationwide inquiry by agents of the Federal Reserve Board shows that the movement toward better conditions was slightly retarded during February principally on account of changes in the prices of basic raw material. Consumers were apparently uncertain as to the trend of prices inasmuch as current purchasing was restricted to immediate needs. One of the encouraging features of the past month was the improvement in employment.

The Board stated that the price reduction in semi-finished and finished steel products, as quoted by independent steel producers, and those in crude and refined oils, disturbed conditions for a time. The month was quiet financially with only a moderate demand for investment securities. Wholesale prices in January declined somewhat less rapidly than in December. The discrimination in purchasing as evidenced in the retail trade brought about movements towards lower price levels. Throughout the agricultural districts it is reported that the mild winter has been highly beneficial to crops and undoubtedly spring truck crops will soon be moving. This fact would indicate a renewed use of motor vehicles in transporting the farm products.

ADD TO FOREIGN TRADE BOARD

NEW YORK, March 7—Three new members have been appointed to the organization committee of the Foreign Trade Finance Corp. They are H. M. Swetland, president of the United Publishers Corp. and the National Publishers Association; W. C. Redfield, former Secretary of Commerce, and Jerome T. Thralls, secretary of the Discount Corp.

DEARBORN OFFICERS CHOSEN

KALAMAZOO, MICH., March 5—The Dearborn Equipment Co. at its annual meeting named the following officers and directors for the ensuing year: President, J. H. Penniman; vice-president, J. W. Bermes; secretary-treasurer, C. S. Bush; directors, the above and H. B. Garvey and William Shakespeare, Jr.

Goodyear Holders Favor Finance Plan

Unanimous Consent of Merchandise Creditors Sought Before Stock Meeting

AKRON, March 7—A canvass made by officers of the Goodyear Tire & Rubber Co. shows that sufficient personal and proxy votes of stockholders have been received to ratify the $85,000,000 refinancing program. It is hoped that when the meeting adjourned from March 4 to March 15 is held practically all of the merchandise creditors will have given their consent. More than 80 per cent already have done so. It is now believed that adoption of the plan is assured. In announcing the adjournment of the special stockholders' meeting, a statement was issued which said:

"Officers of the Goodyear Tire & Rubber Co. announce that they have been advised by the merchandise creditors' committee that owners of more than 75 per cent of the merchandise indebtedness dealt with by the 'plan of readjustment' have consented to the plan. While the company is gratified at the progress made by the merchandise creditors' committee, in view of the large amount involved, the plan cannot be carried out so long as creditors holding any substantial amount of the company's debt have not assented.

"Accordingly, the company does not feel justified in completing the changes in its corporate structure contemplated by the plan until substantially all the creditors have filed their assents with the committee, and the meeting of the stockholders called for to-morrow, March 4, will be adjourned until March 15, by which time it is hoped that the remaining creditors will have signed assents."

It is understood that some creditors who have refused to assent to the plan, are holding out in the hopes that as a last resort, interests friendly to the company will buy them up, and thus enable them to settle their accounts in full for cash rather than to accept part in cash and the balance in prior preference stock. Although it is considered probable that such steps might be taken it is stated that too large an amount of merchandise indebtedness is represented.

To Pay Stock on Contracts

Just what effect this attitude will have upon the final consummation of the plan is problematical. Unanimous creditor assent is sought by March 15. It is understood all merchandise claims of under $1000 will be paid in full. It is also understood that the plan of readjustment stipulates 25 per cent cash payments and the balance in prior preference stock, on all merchandise indebtedness. Men familiar with the details of the refinancing plans say contract creditors will not be paid any cash in settlement of claims, but will receive $125 in prior preference stock for every $100 of indebtedness held.

Cleveland Factories Increase Production

Outlook for March Business Is Pronounced Good—February Much Improved

CLEVELAND, March 5—February's business at all automobile plants in this city exceeded by a good margin the volume in the previous month.

Reports from the Grant factory indicate a very favorable business this year. January's production program of 150 cars was exceeded, and when the books are closed for the month of February the program of 250 cars for the second month of the new year will have been exceeded. Orders are on the books for 200 cars for delivery in March, while the program for March calls for 300 cars. As the Grant Co. is now using the Walker motor exclusively, the latter company also has increased production greatly in the last two months.

The Templar company also has enjoyed good business thus far in the new year. February sales tripled those for January, while March business already booked far exceeds the business done in January.

At the Winton company, where operation has been greatly limited for some time, in common with other factories, production is to be increased on March 15. Already workmen have been notified to report, and machinery has been thoroughly overhauled. The company expects April to be a better month than March, while business booked for March is better than the record for January.

At the Chandler plant it was stated that the volume of business in February was greatly in excess of that in the previous month, and that the management is looking forward to better business in March.

The Peerless management reported an increase in the month just closed over the record for January, while March is expected to prove that a genuine business revival is on.

Allen Motor Reduces Receiver Indebtedness

COLUMBUS, March 7—The affairs of the Allen Motor Co. are in a better position now than they have been since the receivership began, according to a report submitted by a creditors' committee headed by R. C. Wolcott. A reorganization of the personnel has been made whereby the overhead has been reduced $6,600 a month. Orders have been coming in at an encouraging rate. Those now on hand number approximately 300, of which 69 are for immediate shipment with payment upon delivery. No cars are being shipped to dealers who cannot pay cash. Shipments in February numbered 54 cars.

Receiver's indebtedness was reduced $49,000 in February and outstanding drafts were reduced $80,000. It is hoped that by April 1 all receiver's indebtedness can be paid exclusive of receiver's certificates, as well as all bills for current requirements, and that during April some headway can be made in the reduction of the receiver's certificates. Purchases will be confined to actual requirements against bona fide orders for immediate shipments, and no further accumulation of inventory will be permitted. Altogether the situation is more hopeful than it has been at any time since the receivership began.

BUSINESS RENEWALS

EAST PALESTINE, OHIO—The McGraw Tire & Rubber Co. has resumed operations on a limited scale after having been closed for several months. Manufacture of tubes and tires has been begun.

BEREA, OHIO—The Dunham Co., manufacturers of automobile castings, is turning out a considerable quantity of castings for customers in various parts of the country. It has a daily capacity of from 125 to 150 tons.

CLEVELAND, OHIO—The Pennsylvania Piston Rings Co., Inc., manufacturers of individual cast piston rings, started operations on a full time basis March 1 in its foundry and machine shop.

STOCKTON, CAL.—The Croyer Motors Co. has broken ground for the first unit of its new plant in which a new type of tractor will be manufactured. This company formerly made the Sampson tractor but its plant and equipment were sold to the General Motors Corp. The first unit is to be a building 90x440 feet.

PHILADELPHIA—The L. H. Gilmer Co., manufacturers of belting and other woven products, announces that it has accumulated sufficient orders so that the main factory at Tacony is running full time and two departments with double shifts 18 hours a day. The company says that prospects are very bright for a satisfactory year.

SPRINGFIELD, OHIO, March 4—Sales demands are beyond expectations, said officials at the Springfield works of the International Harvester Co. Since the first high speed trucks have been delivered there is a general demand, it was stated. Production at the Springfield works is now under headway. The indications are that the big plant will be called upon to increase the schedule.

SPRINGFIELD, OHIO, March 4—During a visit of officials of the Kelly-Springfield Motor Truck Co. from New York and other points to the plant here it was stated that the indications are that the plant will soon be under headway and that the outlook for the year is encouraging.

Optimism Reigns at N. A. C. C. Meeting

Will Expand Statistical Department—To Join International Commerce Chamber

(*Continued from page* 574)

for investigation discloses that good but reckless drivers are responsible for most of the mishaps which are not due to pedestrians themselves. Strict enforcement of the present motor vehicle laws would do much to remedy the situation. In most states the statutes are adequate for proper punishment of careless drivers, either imposing jail sentences or forfeiture of license.

The directors decided to expand the statistical department of the N. A. C. C. and in the discussion of this subject there was much commendation of the statistical number of AUTOMOTIVE INDUSTRIES. It was felt that by the expansion of the department, further valuable aid would be given such publication in the preparation of statistics of the industry.

It was decided to join the International Chamber of Commerce because it was believed it would be a stimulus to the development of foreign trade. J. Walter Drake, chairman of the export committee, urged the members of the chamber to give their wholehearted support to the Foreign Trade Finance Corp. which recently has been organized.

Toledo Parts Factories Report Larger Orders

TOLEDO, March 7—Allied industries at Toledo are showing signs of business pickup. The Bock Bearing Co. reports that its outlook for March is 50 per cent better than February. The plant here was operated for the first 15 days of last month.

The Tillotson Mfg. Co., which makes carbureters, reported that a few more workers may be put on production later in the month. President H. C. Tillotson says orders are growing but most are being filled out of stock which the company accumulated during the fall.

J. W. Bunting, president of the Bunting Brass & Bronze Co., declared that business was steadily increasing and that his plant would increase its output if improvement continued.

Most automobile manufacturers here believe that 1921 will be a "40 per cent year."

WHITE WORKS TWO SHIFTS

CLEVELAND, March 7—The White Motor Co. now has a working force of 5000, which is divided into two groups of 2500 each. Each group will work three days a week and there will be no change in wage rates at present. About 1200 men were laid off March 1. When men are hired later on it probably will be at a slight increase.

Miller Tire Surplus Nears Depletion

Calls in Stocks to Meet Demands —To Go Slow on New Production

AKRON, March 8—Miller Rubber Co. is the first tire concern to announce that the predicted tire shortage has arrived, By order of Akron officials of the company all available supplies of tires are being brought in from branches in sections of the country where sales are slow, in order to meet the rush demand for orders from dealers in other sections of the country.

Miller has taken this means of meeting heavy spring demands, rather than to immediately quicken production, as it will create a quicker turn-over of stock and enable the company to enter a more stable basis of production when an increase of marked proportion is deemed necessary.

This same policy is being adopted by practically all other Akron tire concerns which are endeavoring to have factory stocks completely absorbed before any heavy production increases are enforced. All factories report surplus stocks diminishing rapidly, and have issued statements indicating that as soon as such supplies are completely exhausted, production will be increased commensurate only with actual current demand.

This is taken to mean that it will become the policy in the rubber industry in the future not to provide too far in advance, but to keep production on an even keel and parallel with actual demand, so as not to clog dealers' shelves with surplus stocks, and so as also to prevent a repetition of the crisis and necessary heavy retrenchment in the tire industry, created when sales slumped last year. Had rubber factories at that time not had surplus stocks on hand, and had they reduced production so as to hold it even with actual demand, practically all such concerns would have breezed through the depression period with small losses.

DETROIT EMPLOYMENT GAINS

DETROIT, March 4—The Employers' Association of Detroit reports 8008 additional men employed in the 79 factories affiliated with the association during the last week in February. On March 1 the 79 firms were employing 62,878 men. This is a gain of 17,905 since Feb. 1. Constant addition to the employees' roll at the Ford plant has had much to do with the increase.

JIG BUSHING TO START WORK

PONTIAC, MICH., March 4—The Jig Bushing Co., makers of bushings for automobile plants, will start production on a full line of its products at its new factory here, April 1. The concern is a new one in the local field and is owned by O. R. Briney of Pontiac and L. M. Richards of Cleveland.

CARS FOR CLERGYMEN TO DOUBLE EFFICIENCY

CHICAGO, March 7 — "Every pastor should have a car," is the assertion made in an editorial printed by the *Northwestern Christian Advocate*, one of the official papers of the Methodist Episcopal church.

"The minister's efficiency is doubled, trebled and even quadrupled by the use of the 4-wheeled chariot of the Apocalypse," says Dr. E. Robb Zaring, the editor. "He can visit sections where shoes, horse or human, could not penetrate. Every pastor should have a car, every rural pastor particularly. The people that the rural pastor serves probably have theirs. Pass prosperity to the parson."

Improvement Gratifies Milwaukee Industries

MILWAUKEE, March 4—Concerns in the automotive parts and equipment industries in Milwaukee and vicinity report a gratifying betterment in their business, which consists of something more than feeling, according to the latest review of local conditions compiled by the First Wisconsin National Bank of Milwaukee. The summary says:

"One company reports a sales increase during the past month of about 100 per cent over the previous month.

"The automotive industries do not expect to do any such an amount of business as last year. Only a fair year is expected. Necessary replacements of parts and accessories in itself provides a medium of business for firms engaged in this line.

"Milwaukee motor truck interests report improved prospects. The outlook for trucks this year looks a little better than that for passenger cars. Future prices in parts and accessories depend upon what happens in the steel market. None of the Milwaukee plants are yet operating above 50 per cent of capacity. Little dependence is placed on export business for this season."

PETERS CUTS BODY PRICES

BALTIMORE, March 5—The Peters Auto Body & Spring Works has made a 15 per cent reduction in the prices of commercial automobile bodies. This was made after a careful study of the present situation by Charles H. T. Peters, who decided to give the public advantage of lower prices without reducing the quality of the bodies built.

OAKLAND BODY PLANT STARTS

PONTIAC, MICH., March 4—The Oakland Motor Car Co. resumed operations in its body plant here, giving employment to 200 men. The Standard Parts Co., which has been closed for some time, expects to resume next week with a force of 150 men.

Australia Looks for Return to Buying

Improved Crops Expected to Bring Easier Conditions—Favor British Products

SYDNEY, NEW SOUTH WALES, Jan. 28—(Special Correspondence)—Automobile trade in New South Wales has slowed up seriously since last October because of the expectation of a fall in prices. Many prospective purchasers canceled their orders and prospects have been hard to find. The one encouraging factor in the situation is that there are comparatively small stocks on hand in Australia and the supply on hand will not last more than four months even with the few sales now being made.

The shortage of stocks is due to cancellations by dealers when the buyers' strike began, and further cancellations resulting from inability to remit payments because the banks could not sell Australian drafts. Added impetus to cancellations was given by the expected advent of European cars. The Government and newspapers have urged that English goods be pushed for patriotic reasons and this has had its effect.

Purchasing power in Australia has been limited because of short crops for the past few years resulting from droughts. The drought has now broken, however, and it is expected that many persons who have been clinging to their dilapidated motor vehicles will soon be in the market for new cars. A marked increase in business is expected by May or June if prices become firm.

Another serious factor is the high price of gasoline, which is now selling at $1 a gallon. There is slight probability of production of gasoline in this country in the near future.

While motor trucks are not popular in Victoria and South Australia, there is a good market for them in New South Wales, which has more of them than all the rest of Australia put together.

Truck Manager Finds Service Methods Wrong

NEW YORK, March 4—Manufacturers, dealers and service men alike were criticised last night by C. R. Collins, general manager of the National Association of Commercial Haulers, in an address before the Automotive Service Association of New York. He cited many instances to prove that the service is not satisfactory and told of the growing installation of private repair shops by large fleet owners and of the associations of passenger car and small truck owners, maintaining cooperative shops.

Collins said that if service conditions do not improve materially, some system such as the English and Continental guilds will step into the place and all purchases and repairs will be made collectively and without the necessity of the middleman.

Trucks Gain Trade As Railroads Slump

New England Shippers Find Rail Lines Inefficient and Rates Unsatisfactory

BOSTON, March 5—It has been admitted that Boston business houses have been driven to the use of motor trucks because of the breakdown of the railroad transportation system in New England.

Action by the board of directors of the Boston Chamber of Commerce in voting to ask an investigation of New England railroads by the Interstate Commerce Commission, and that of the executive committee of the New England Traffic League in sending an open letter to the directors of the New England roads calling for the removal of heads of these companies, created a decided stir in railroad circles yesterday.

While both organizations aim to bring about the same result—a more efficient handling of New England railroads—they have adopted different methods, the former making its appeal to Washington, whereas the Traffic League wants to deal directly with the directors of the roads.

Both organizations set up the claim that there should be an inquiry as to whether the roads are being operated efficiently and economically.

Speaking through the transportation committee of the Associated Industries of Massachusetts, which is the clearing house for more than 1600 interests in this State, the industrial forces of the Commonwealth have emphatically declared that the proposed 10 per cent advance in steam railroad rates will not solve the railroad problem for New England.

In a statement issued to-day by the committee, of which W. P. Libby, traffic manager of the Plymouth Cordage Co. of Plymouth is chairman, the Associated Industries of Massachusetts said:

"The Associated Industries of Massachusetts has learned that 250 industries are now using motor trucks in competition with the railroad, and this results in a net loss in revenue to the New England railroads of approximately $2,000,000. The 1914 census of manufacturers shows that there are in New England 19,660 separate and distinct industries, and this may possibly furnish a proper basis upon which to estimate the total net revenue loss to our New England railroads.

"The investigation of the motor truck competition reveals the fact that there are hundreds of instances of great differences in costs. A few of the items are as follows:

"Boston to Lynn, shoe findings, railroad rate 34½ cents, motor truck rate 22 cents.

"North Dighton to Boston, textiles, railroad rate, 37 cents, motor truck rate 35 cents.

"Boston to Fitchburg, confectionery, railroad rate 46 cents, motor truck rate 40 cents.

"Lowell to Boston, the railroad rate on the first three classes comprising thousands of articles ranges from 31 cents to 46 cents per 100 pounds, while the truck rate ranges from 30 to 40 cents.

"These specific instances are much more impressive in consideration of the fact that the motor truck rates in every instance include store door pick-up and delivery service, whereas to the rail rate must be added for the same service a surcharge of from 15 to 25 cents per 100 lbs. or per package for delivery.

"Another factor that should also be taken into consideration is the fact that the average saving in time by truck transportation as against railroad service on 144 routes is 44.65 hours per route.

"It is no secret that there is a movement on foot to establish motor truck and steamship service on points such as Bridgeport, New Haven, New London, Providence, Fall River, New Bedford, Boston, Beverly, Portsmouth, Portland, Bangor, etc. The establishment of such service in co-ordination with the truck lines from the important industrial centers will have a disastrous effect on the revenues of the railroads."

Reduction of labor costs, these Bay State industries claim, is the only relief for New England railroads.

African Gold Coast in Market for Trucks

OTTAWA, ONT., March 4—Writing to Ottawa from the Gold Coast Colony, West Africa, Canadian Trade Commissioner W. J. Egan states that the colony will shortly be in the market for motor lorries. The standards required are to carry a load of ½ ton and 1 ton. The total weight of the lorry and one ton freight must not exceed 5000 lb. while the ½ ton capacity motor lorry is naturally expected to weigh less.

The price set by the Government is from $2000 to $2500 but they may consider $3000 if necessary.

If the running mechanism is such that a speed of not over 15 miles per hour can be made this will be a strong recommendation. A certain lorry has been in use but the desire of the authorities is to get a lorry better suited to their needs than the present one, that is, one that will stand up against the strain of a tropical country and give a reasonable time of service. Drivers are raw natives so a fool-proof style of lorry is necessary and if the proper car can be introduced this will be made a standard and as the transport of the country is very largely motor, orders for vehicles would amount to hundreds each year.

Orders will be placed in April this year and prices of spare parts and the capacity of the factory should be given with any other particulars thought advisable.

FORD CLEANS OUT GROCERIES

DETROIT, March 4—Ford Motor Company is liquidating the stock of groceries and will discontinue its grocery store as soon as stocks have been exhausted. The shoe, clothing, drug and meat stores, however, will be continued. Mr. Ford assigns his reason for closing the grocery to rapid downward trend of grocery prices.

N. A. C. C. Points Out New Truck Markets

School Consolidations Necessitate Vehicles for Pupils—Rail Rates Make Business

NEW YORK, March 4—Twelve thousand consolidated rural schools in the United States are using vehicles for transporting pupils. About half the equipment is motorized and the remainder horsedrawn. The National Automobile Chamber of Commerce has sent a bulletin to its members pointing out the sales possibilities in this field. It is pointed out also that 194,000 one-room schools not yet consolidated, promise a future motor vehicle market. Pennsylvania now has under consideration 275 new consolidations.

The use of motor vehicles for consolidated schools has been urged by P. P. Claxton, United States Commissioner of Education. The bulletin explains that J. C. Muerman of the United States Bureau of Education has provided the following suggestions on body styles:

1. Top ventilators are desirable.
2. Preferable to have driver's seat in the same compartment as passengers, so that he can keep control of children.
3. As much weight as possible needed on front wheels. Present tendency is for large school buses to have too much weight on rear wheels.
4. Two exits important, in case of fire, capsizing, or stalling in drifts.
5. Where four rows of seats, running lengthwise of bus; are provided, ample aisle space should be allowed, using maximum possible width of body.
6. Upholstery—if not too expensive, removable khaki upholstery over leather or leatherette would be preferable to plain leather currently used, as the khaki could be removed and washed.

Another bulletin sent out by the motor truck committee of the N. A. C. C. states that if railroad rates are further advanced in Massachusetts, 532 members of the associated industries of that State have stated that they would use motor trucks exclusively. In many cases this would necessitate new fleets.

A survey recently completed by the truck committee shows that 2765 Maryland farmers are using trucks. A similar survey in Kentucky indicated that there was a real need for more trucks in 13 counties.

BRITISH TO TEST TRACTORS

LONDON, Feb. 8—(*Special Correspondence*)—The 1921 British tractor trials will be conducted by the Society of Motor Manufacturers and Traders and regulations and entry blanks are now being published. One of the features of this year's demonstration will be fitting a recording dynamometer to every tractor in the field, which dynamometer will be carried throughout the demonstration. A special machine has been designed for which world patents are claimed.

Citroen Cuts Price to Absorb Taxes

Takes Action as Protest to Government — French Market Poor—Finances Easier

PARIS, Feb. 16—(Special Correspondence)—Citroen has made another cut of 10 per cent in the price of his cars, thus bringing the price of the four-seater down to 14,310 francs. The sedan is listed at 21,600 francs. This cut is made in the form of a 10 per cent discount to cover the luxury tax applied in France on all automobile sales. Instead of this tax being paid by the client, Citroen now pays it for the client, and makes use of this publicity to protest against the Government tax.

Citroen still holds the position of marketing the cheapest car of French construction on the market. Renault, who is now in direct competition with Citroen, with a four-cylinder 10 hp. four-passenger model, officially maintains his price at 21,000 francs, but as dealers hold stocks, sales are often made at 16,000 francs, and sometimes a little lower.

Since the new year the revival of business on the French market has been very slight. There is an impression abroad that further price reductions may be expected shortly, and because of this the public is holding off. De Dion Bouton is contemplating a cut of 4000 francs, thus dropping the price of the 10 hp. model from 21,000 to 17,000 francs. Price reductions up to the present have not given the results that were expected. In the case of Ford, who initiated the movement in France, there was no result at all.

A net profit of 7,126,383 francs for the year 1920 was declared at the annual meeting of the Lorraine-Dietrich Co., compared with 12,379,127 for the year 1918-19. This concern has two independent branches, the factory at Luneville being interested chiefly in railroad material, and the works near Paris producing automobiles.

The automobile program of the company consists of a 15 hp. 6-cylinder automobile of high grade, but laid out with a view to cheap quantity production. Although the car was shown at the automobile exhibitions more than a year ago, production has not yet begun.

Schneider to Make Tractor

The Schneider Co. at Le Creusot, the biggest armament and general engineering concern in France, has secured a predominating control of the Brasier Automobile Co. It is intended, under the new management, to continue work on the new Brasier factory at Grenoble, where the four-wheel drive Pavesi tractor will be built. This factory was begun during the war by a group of French automobile manufacturers, and was used by them for the production of aviation engines. As hydroelectric power is readily and cheaply obtained in this district, it was decided to extend the works after the armistice and undertake tractor construction. The Pavesi machine is of Italian origin, and is now being built at Grenoble under license. The French car department has approved this type of tractor and has placed orders for a certain number.

The Zebre Automobile Co. being in financial difficulties, a meeting has been called to consider the advisability of either winding up the concern or reorganizing it under new management.

Recall Dealer's Sales Rights

The automobile department of the French company of Gaston, Williams & Wigmore has practically ceased to exist. This firm had exclusive selling rights for Voisin cars, a monopoly of the sale of G. N. cyclecars on the Continental market, and through its subsidiary company, Gaston, Ltd., had the Citroen exclusively in Great Britain.

Voisin has decided to do his own marketing. The commercial service of the G. N. cyclecar is being handled by the Salmson company, builders of this machine, and Citroen will very shortly open up his own English selling organization. Voisin is completing tests of a high-grade 12-cylinder automobile, which probably will be uncovered to the public at the next Paris show.

Daimler to Re-enter French Car Market

PARIS, Feb. 18 (*Special Correspondence*)—The arrival of directors of the Daimler Motoren Gesellschaft of Stuttgart of this city leads to the belief that the leading German automobile company is about to re-enter the French market. The German Daimler Co. possesses handsome showrooms in the Avenue des Champs-Elysees, Paris, and is entitled to take possession of them. At the present time these buildings are being used temporarily by a philanthropic organization for the benefit of French soldiers. The Daimler workshops and spare parts depots, at Suresnes, in the suburbs of Paris, were pulled down during the war and the ground used for an extension of the French arsenal.

Up to the present no German automobile firm has sought to get on the French market by direct representation. The Benz Co. of Mannheim has a dealer in France, but he has not yet received cars for sale. The Bosch Magneto Co. of Stuttgart has a selling organization in Paris and is doing a small amount of business in magneto and lighting sets.

Report Ford Has Sold Canadian Interests

DETROIT, March 10—Confirmation is not obtainable of a report that Henry Ford has sold his Canadian interests for $4,000,000. The report has it that the sale includes rights in all British possessions except England, Scotland and Wales. Neither Henry Ford nor Edsel Ford could be reached to discuss the report.

United States Ships 1516 Cars to Belgium

Exports for Year Surpassed Only by France—Higher Tariffs Urged for Protection

BRUSSELS, Feb. 15 (*Special Correspondence*)—In 1913 Belgium imported 1100 automobiles and exported 3100. During 1920 the imports were 4468 complete cars and chassis, and the exports 1729 cars and chassis. France did the greatest volume of business with Belgium, the number of vehicles being 1647, composed of 1061 complete cars and 586 chassis. America came a close second with a total of 1516, of which 1380 were complete cars and 136 were chassis. Germany sent 528 automobiles into Belgium last year. Great Britain was Belgium's best client, for during the year she took 352 complete cars and 256 chassis. Holland was the next best customer.

Country	Exports from Belgium		Imports into Belgium	
	Complete Cars	Chassis	Complete Cars	Chassis
Germany	7	20	466	62
United States	4	3	1380	136
France	95	62	1061	586
Great Britain	352	256	120	38
Italy	2	7	235	234
Spain	127	..	..	..
Holland	225	..	55	..
Portugal	134	..	..	..
Other countries	253	191	87	8

The Belgian industry is divided, at the present time, into two hostile camps. Importers, for the most part representing French and American firms, are using all their influence to prevent the Government increasing the import duties on automobiles, while the manufacturers are sparing no effort to get Government protection, in the form of increased duties, against foreign competition. The present Belgian import duty is 240 francs per 100 kilos, compared with 80 francs before the war.

Manufacturers claim that as the weight of cars has not increased, while their value has tripled at least, the percentage is no higher now than it was in 1914. A high-class foreign car catalogued at 30,000 francs pays about 2400 francs import duty, being equivalent to 8 per cent of its value, which is the same percentage as in pre-war days. On this account the manufacturers of Belgium claim that they should be given a 45 per cent ad valorem import duty.

A Government decree on this subject is now in preparation, but it is not known whether the new duty will be 33½ per cent, as in England, or 45 per cent as in France.

INDIA INCREASES CAR TARIFF

WASHINGTON, March 8—According to a cablegram from Consul General A. W. Weddell, Calcutta, under date of March 1, the Government of British India has increased the duty on automobiles from 7½ per cent ad valorem to 20 per cent, effective March 1.

Many Plants Place Orders for Parts

Hold Over Shipments Released for Delivery—Better Action on Payments

NEW YORK, March 7—Indisputable evidence of improvement in business conditions was given at meetings of groups A and B of the credit department of the Motor and Accessory Manufacturers Association held on the same day at Cleveland and New York. Upon request from headquarters, members attending were prepared to give information regarding the placing of new orders, release of shipments on old orders, collections as compared with the previous month and production of cars. It was disclosed at the two meetings that the following manufacturers have placed orders for new material in varying quantities:—

O. Armleder Co.
Briscoe Motor Corp.
Jas. Cunningham Son & Co.
Dort Motor Car Co.
Elgin Motor Car Co.
Ford Motor Co.
Franklin Mfg. Co., H. H.
Gardner Motor Car Co.
General Motors Corp. (Buick Div.)
General Motors Corp. (Cadillac Div.)
General Motors Corp. (Sheridan Motor Car Co.)
Gramm Bernstein Motor Truck Co.
H. C. S. Motor Car Co.
Haynes Auto Co.
Hendee Mfg. Co.
Hupp Motor Car Corp.
International Motor Co., Inc.
Lincoln Motor Co.
Locomobile Co.
Maxwell Motor Co.
Moon Motor Car Co.
Nelson Motor Car Co.
Reo Motor Car Co.
Studebaker Corp.
Stutz Motor Car Co.
Yellow Cab Mfg. Co.

Releases of shipments on old orders were reported as being received by members from the following:

Acme Motor Truck Co.
Auburn Auto Co.
Autocar Co.
Briscoe Motor Corp.
J. I. Case Threshing Machine Co.
Chandler Motor Car Co.
Chevrolet Motor Co.
Cleveland Automobile Co.
Commercial Truck Co. of America.
Day-Elder Motor Corp.
Diamond T Motor Car Co.
Dodge Bros. Inc.
Ford Motor Co.
Franklin Mfg. Co., H. H.
General Motors Corp. (Buick Div.)
General Motors Corp. (Cadillac Div.)
General Motors Corp. (Oakland Div.)
General Motors Corp. (Olds Div.)
Graham Bros.
Grant Motor Car Corp.
H. C. S. Motor Car Co.
Hudson Motor Car Co.
Hupp Motor Car Corp.
Liberty Motor Car Co.
Lincoln Motor Co.
Locomobile Co.
Mercer Motors Co.
Moon Motor Car Co.
Nash Motors Co.
National Motor Car & Vehicle Co.
Northway Motors Corp.
Packard Motor Car Co.
Pierce-Arrow Motor Car Co.
Reo Motor Car Co.
Standard Steel Car Co.
Stevens-Duryea, Inc.
Studebaker Corp.
Templar Motors Co.
Walker Vehicle Co.
Ward Motor Vehicle Co.
White Co.
C. H. Wills & Co.
Yellow Cab Mfg. Co.

The quantities reported in both instances vary quite materially, as do the number of members with whom new orders or releases have been placed.

A report prepared by C. A. Burrell, manager of the credit department, says:

"As regards payment of accounts to our members, there seems to be comparatively little change from their experiences during January. In but few instances are accounts being paid in full, when due, or even for some time after due date. In the great majority of instances paper is being offered in settlement of accounts and being renewed in whole or in part when it becomes due. There does, however, seem to be a tendency to take care of accounts, either by partial payments and note or by all paper, somewhat more promptly than during the last few months.

"Members of the groups generally report a better condition of affairs than existed before the first of the year, and the prevailing tone seems to be more optimistic. Reports made by those who have endeavored to arrive at a percentage seem to indicate that business is ranging about 20 per cent to 33-1/3 per cent of what might be considered normal, though the latter figure is probably somewhat high.

"Labor conditions show no material change. Manufacturers in many instances are doing their level best to furnish as much employment as possible for their help, in some cases alternating between different groups of employees in an effort to satisfy all as nearly as possible."

Zeppelin Negotiates for French Financing

NEW YORK, March 4—Advices from London say that great indignation has been aroused in Germany by the report that negotiations are in progress for a French company to acquire a controlling interest in the Zeppelin company.

In the course of an interview, Director Coleman of the Zeppelin company states that his company reluctantly arrived at the conclusion that it can no longer exist as a purely German enterprise, and that it was essential that it should be converted into an international organization.

With that end in view he admitted he was in negotiation with a French company in Paris, but the negotiations have not yet advanced beyond the preliminary stage.

A. E. A. TO MEET MARCH 30

CHICAGO, March 7—The Automotive Equipment Association has called a meeting of its directors and membership committee to be held at the Congress Hotel, March 30 and 31. The meeting will be equally divided between jobbers and manufacturers, and separate sessions will be held to confer on questions of interest to them, after which a joint session will be held to discuss constructive measures. Questions taken up in a preliminary way will be further discussed at the June meeting.

Moock Seeks Ideas on Car Chautauqua

Manufacturers' Aid May Be Asked to Defray Expenses of Dealer Education

ST. LOUIS, March 7—A motor vehicle Chautauqua to educate small town dealers in all phases of their business has been proposed by Harry G. Moock, general manager of the National Automobile Dealers Association, and he is now getting the ideas of leaders in the industry on the subject as well as gathering data which would be of value in putting his plan into effect.

It is Moock's idea that there are thousands of dealers in the smaller towns who never have had a chance to learn the most modern methods of conducting their business, such as cost systems and the latest idea in salesmanship. He proposes to hold sessions of the Chautauqua at the principal distributing centers and make the sessions available to all dealers upon the payment of a nominal fee which would insure their interest in the courses provided.

If the plan is put over, a faculty of experts in all branches will be provided for the traveling university. They would be qualified to teach service, accounting and selling. Their lessons would bring out the most advanced ideas in all branches of the business and it is believed dealers would get knowledge and ideas which would prove invaluable to them.

No definite plan has been worked out for financing the project, but it is believed the manufacturers would be sufficiently interested in the project to help defray the expenses. The returns they would receive from the increased selling ability of their dealers, it is believed, would recompense them many times over for any expenditure they might make in this direction.

DEALERS DISCUSS CONTRACTS

MACON, GA., March 4—Dealer contracts and franchises under which they sell automobiles and motor trucks comprised one of the principal subjects discussed at a meeting here of automobile dealers from 20 Georgia counties surrounding Macon. An open discussion relative to plans and methods of selling used motor cars was also an important feature of the meeting, the dealers of the various towns exchanging their ideas.

NAME FINANCE DIRECTORS

BOSTON, March 5—Complete new directorates for the Mutual and Commercial Finance corporations, the automobile finance companies promoted by the H. V. Greene Co., have been elected at adjourned annual meetings of the two concerns. The new directors are Patrick F. Sullivan of Lowell, Samuel L. Powers, Gen. John H. Sherburne, George A. Rich and Guy W. Currier. Arthur R. Stubbs was elected treasurer.

Tax Removal Helps Ontario Business

Demand for Cars Follows Removal from Luxury Classification—Reserve Stocks Low

TORONTO, March 8—The motor business in this city and throughout the Province of Ontario has improved perceptibly during the past month. January business was not more than 60 per cent of January, 1920. The selling season here opened in February and this year the open winter has been a needed stimulant.

One factor that has contributed to stimulation of sales was the removal of the luxury tax, which removal is equivalent to a very pronounced price reduction. On the Cadillac touring car the removal of the luxury tax has reduced the price from $7,300 to $6,475. On a Chevrolet model 490 the reduction is approximately $125. The reduction of the Roamer touring car is from $5,875 to $4,950. Some of the Ontario distributers have been compelled to absorb the luxury tax as they had paid it on cars purchased but which were not sold when the tax was removed. In some instances the manufacturers have shared the absorption of the tax with the dealers on a fifty-fifty basis.

The Toronto dealers were not overstocked with cars when business opened in February. Recently Cadillac sales have been 60 per cent of a year ago on closed cars, and 40 per cent on open cars. In February Franklin business approximated 50 per cent of normal. Motor trucks started selling in February, the comprehensive highway program which has been under way for two years serving as a good stimulant. The Packard branch has made recent sales to industrial organizations, as well as to organizations engaged in highway construction.

The Hyslop organization, selling Cadillacs for the province, and also having a large accessory department with salesmen traveling all of Ontario, has found accessory business is approximately 100 per cent. Increased sales effort has been necessary to keep it at this figure.

Expect 65,000 Output in 1921

Robert H. Combs, operating the Prest-O-Lite Co. of Canada, Ltd., and the National Carbon Co., which manufactures Prest-O-Lite batteries for Canada, and Columbia dry cells, estimates that 80,000 motor cars were built in Canada in 1920, and that Canada has factory capacity for 150,000 automobiles per year. The production of Canadian factories for 1921 is problematic but Combs believes it will approximate 65,000 vehicles, which is 15,000 less than last year.

The leading factories producing in Canada are Ford, McLaughlin, Chevrolet, Willys-Overland, Grey-Dort, Studebaker, Maxwell, Briscoe, Chalmers, and two smaller concerns. Ford has capacity for approximately 100,000 cars per year, and estimates on the capacity of some of the others are: Grey-Dort 15,000; Chevrolet, 12,000; McLaughlin, 10,000; Willys-Overland, 10,000; and Studebaker, 3500.

There are in Canada four truck manufacturers with whom business is slow.

The Prest-O-Lite Co. of Canada, and the National Carbon Co. are located in a new factory finished a year ago. It is a modern plant in every respect, fitted with production machinery. The dry cell factory is working at 100 per cent and the starting and ignition battery department at 40 to 50 per cent.

The tire business in Canada has been slowed down practically the same as in the United States. This applies to the Goodyear Tire & Rubber Co., the Dominion Rubber System, which is the United States, Dunlop Tire & Rubber Co., and the Gutta Percha Rubber Co. Firestone is building a new factory in Hamilton.

Durant to Try Out Experimental Cars

NEW YORK, March 8—W. C. Durant expects to have completed by the last of this month the experimental cars which will be given thorough tests before they are put in production by Durant Motors, Inc. No details regarding them have been made public but it is understood there will be two models, the lower priced of which will sell at less than $1000.

While many cities are hoping they will get one of the Durant factories no statement in regard to locations has been made since the decision to locate one in Flint and another on the Pacific coast. Even the Flint site has not been settled upon.

Durant Motors stock is now quoted on the curb market at around 20 and it is understood there will be another issue of 100,000 shares of no par value common at $20 a share.

Production and distribution personnel are being built up. The latest announcement is that Roland T. Meacham of Cleveland has been appointed Ohio representative.

Receiver Seeks Consent to Forge Company Sale

CLEVELAND, March 7—Creditors and stockholders of the Forest City Machine & Forge Co. have been directed to show cause March 19 why the receiver, Francis W. Treadway, should not sell all the assets of the company to I. T. Kahn of Cleveland who has offered $300,000 for them. An appraisal made last June fixed the value of the assets including land, buildings and machinery at $740,802.

The total liabilities of the company are $352,195. There is a first lien of $57,500 against the property on the purchase price of the land as well as a mechanics lien for $14,462 and receiver's certificates amounting to $15,000. If Kahn's offer is accepted, there will be about $200,000 for distribution among the creditors. The receiver states that all attempts at reorganization have failed and that he has been unable to get any other offer for the property.

Congress Condemns Army Car Purchases

More Assertions of Wasteful Methods Made—Attack Contracts Recently Signed

WASHINGTON, March 8—Bitter partisanship marked the final report of the House Select Committee on Expenditures in the War Department, in which the policy pursued by the Secretary of War in the purchase and sale of automotive equipment used by the American Expeditionary Forces is condemned. The Committee contended that its inquiry "shows the power wielded by the motor industry, or a part of it at least, through the War Industries Board, was disadvantageous to the interests of the Government in time of war."

The majority report charges that material worth millions of dollars was wasted and misapplied, that the War Department failed to provide adequate motor equipment for the overseas forces, that thousands of automobiles and trucks were wrecked because of the lack of spare-parts, that tires valued at from $3,000,000 to $20,000,000 were left to rot at one place alone, that no American-built tanks reached the front, and that the War Department paid excessive sums for motor equipment. The Graham Committee denounces the policy pursued by the Secretary of War in still purchasing trucks.

The Graham Committee was divided along party lines. The minority report contends that the report of the majority is biased, erroneous, and totally misleading. They point out that mistakes were inevitable in the great war and that the majority gives no recognition to the accomplishments of the Army. The minority claims that "the majority ignored the fact that it is in evidence in the record that the shortages (in motor transport equipment) were primarily due to the lack of adequate sea transportation."

In this public denouncement which the committee will undoubtedly spread broadcast, an attack is made upon the Secretary of War for his approval of an order in February, 1920, over the objection of the Quartermaster General, for the purchase of 75 trucks, known as the "Militor," at a cost price of $8,000 each, totaling with additional tires and spare parts, $726,000.

The committee further insists that the War Department "has paid out to the Militor corporation a total of $1,280,213 for 75 trucks, whereas the same company offered to produce 500 trucks for only $274,000 more. Eighty-one Militor trucks are to cost $2,063,903.20.

LOUISVILLE STARTS SALES

LOUISVILLE, March 7—Though sales during the week of the thirteenth annual automotive show were about 50 per cent less than last year, according to conservative estimates, they have increased since the close and a general revival of trade is in progress.

February Production Shows Large Gains

Shortage of Materials in Two Factories Prevents 40 Per Cent Increase

DETROIT, March 9—Indisputable evidence of the upward trend of the automotive industry is reflected in the step-up in production in Detroit territory during February as compared with January, reports showing a total production in February of 53,040 against 14,615 the previous month. These figures include 31 factories in Detroit and Michigan, and Willys-Overland and Knight plants in Toledo.

What appears to be an increase of approximately 38,000 in the February figures, includes Ford production in Highland Park and branches, totalling 35,000 cars and trucks, about 10 per cent of which were trucks. With the Ford figures eliminated, increase in February was 3425. Ford figures were not included in the January totals because the Highland Park plant was closed, although, according to a statement by Henry Ford, approximately 30,000 cars and trucks were assembled in the assembly branches.

The increase was general throughout the territory, though sharp decrease has been noted in the figures of two of the largest producers, due to various causes. This prevented what otherwise would have been an increase of about 40 per cent in production over January. The instances of decrease were not due to recession in demand, but rather to lack of certain materials, lack of complete working organization due to employees having left when depression became acute, unbalanced inventories which forced certain departments to remain idle while others were working steadily, and similar handicaps brought about by the long period of depression.

March to Extend Increases

That March production will be far ahead of February, with all indications pointing to steady improvement, is certain, in the opinion of leading manufacturers who already have started out on greatly increased schedules. Studebaker plants, which were building 525 of the larger cars in the Detroit plant each week during the first part of February, closed the month with a total in Detroit of 2500 and started in March 1 on a schedule of 665 weekly. The plant has not taken all the men back, but rather increased working time to five days a week instead of four. A schedule of five and a half days will be entered on April 1.

Paige production in February jumped to approximately 63 per cent of normal, and the plant is now operating on a 75 per cent production basis, or about 72 cars daily, according to President H. M. Jewett. The big demand for cars, Jewett said, necessitates a gradual step up until it will be the greatest output in the company's history by April 1. It is expected to hit normal, 90 to 100 cars daily, in a few days. Paige is building trucks only on orders, though Jewett reports the truck end as "showing signs of life."

Packard reports good sales demand, and they are adding to the working force each day. Vice-President Roberts says trucks are moving and activity in that end will increase steadily. The company produced about 30 per cent of normal in February. The Dodge plant is still down and officials have not announced the opening date.

Reo is again working 4000 men full time and 1000 half time. The plant built about 2100 cars and speed wagons during February in ratio of three speed wagons to one car. The company is now producing about 75 per cent of normal—approximately 120 daily.

Hupp built about 700 cars in February and has started on a schedule of 1000 for March. Officials report a steady improvement.

Buick is working 65 per cent of the normal force full time and building about 200 cars daily. One thousand seven hundred cars went to owners in January and 2900 cars in February, with prospects for March of double that total, according to A. B. Batterson.

60 Per Cent for Olds

Olds built about 60 daily in February, chiefly smaller cars. This work jumped to 90 daily, yesterday's output, which is about 60 per cent of normal. Dort is moving conservatively, and while dealers report many prospects and improved actual demand, production will be increased slowly and in keeping with sales. The company built 700 cars in February.

Chevrolet is working a full force part time and during February produced around 85 cars daily.

The Hudson-Essex February output was about 15 per cent of normal.

Exports of Automobiles, Airplanes, Trucks, Farm Tractors, Motorcycles and Parts for January, 1921, and Seven Previous Months

	Month of January				Seven Months Ending Jan.

Banks Would Combine All Willys' Interests

NEW YORK, March 9—Bankers' committees for the Willys Corp. and the Willys-Overland Co. are working together to adjust the closely interwoven affairs of the two companies. Considerable progress in this direction already has been made. While the greatest reticence is maintained, it is understood that nine-tenths of the bank creditors already have agreed to an extension of time for the payment of loans. In the case of the Willys Corp. this extension would carry maturities to May 1.

While the banking interests identified with the two companies are by no means identical, it is understood that they are in practical agreement on what should be done. So far as can be learned, their program calls for a consolidation in one corporation of all the interests with which John N. Willys is identified.

No More Mails for Car Speed Contests

WASHINGTON, March 9—Automobile manufacturers and dealers staging speed and endurance contests in the transportation of mails will not be permitted to carry postal matter without advance authority in each case from the Post Office Department. An order was issued here to-day by Otto Praeger, second assistant postmaster general, advising postmasters throughout the country that no dispatches of mail matter for tests or experimental purposes involving automobiles, airplanes, or other vehicles will be permitted without special authority.

Complaints have been made to the Postmaster General that persons presenting themselves to be employees of the postal service have applied to postmasters for mail matter to be dispatched on certain test trips of automobiles, and also for mail equipment.

INDUSTRIAL NOTES

Dwight P. Robinson & Co., Inc., engineers and constructors of New York, has opened branch offices in Montreal in the Dominion Express Building. Alexander C. Barker, vice-president, is in charge of the office.

Hunter Motor Car Co., which recently purchased a site at Harrisburg, Pa., will begin production of passenger cars about July 1.

Auto Specialties Co., St. Joseph, Mich., has bought the patents of the Burgess Shock Absorber Co. and, after completing improvements of the plant, will enter upon the manufacture of shock absorbers.

American Broach & Machine Co., Ann Arbor, Mich., is building an addition which will permit of employment of 60 men in addition to the present factory force of 40.

Independent Pneumatic Tool Co. has moved the location of its Pittsburgh office to 718 Bessemer Building.

Michigan Copper & Brass Co., Detroit, is working on a production 15 per cent of normal.

A. C. Mannweiler Lamp Co., Fort Wayne, Ind., has changed its name to the Anthony Wayne Lamp Co. and has moved to a new location. Additional equipment has been installed and the company is now in a position to manufacture large lamps of all types.

Rauch & Lang Occupies New Chicopee Factory

SPRINGFIELD, MASS., March 4—Rauch & Lang, Inc., now are settled in their new factory located on a 14 acre tract at Chicopee Falls. The plant is entirely new and was built and equipped especially for the manufacture of the Rauch & Lang electric automobile. It has approximately 100,000 ft. of floor space on one floor of brick and steel saw tooth construction with an open area 30 x 32 ft. between posts. Construction engineers have declared the plant one of the best in the country for the manufacture of automobiles.

Bodies are being built by the Baker Rauch & Lang Co. of Cleveland, but the chassis parts are being manufactured almost entirely at Chicopee Falls. The company reports that the number of orders coming in exceeds expectations and it looks for a good spring business.

Dodge Power Plant Ready for Service

DETROIT, March 4—The new $3,500,000 power plant, one of the units in Dodge Brothers $8,000,000 expansion plan, has been completed. The power plant was built by the Dodge Brothers construction department entirely and safeguards the factory against future emergency such as the breakdown of the Detroit Edison plant last year, upon which practically all Detroit factories were dependent. The power plant is designed for an installed capacity of 40,000 K. W. and requires approximately 25,000 gal. of water a minute for each 10,000 K. W. unit.

In the absence of a natural water supply near the factory or space sufficient for establishing a cooling reservoir, it became necessary for Dodge Brothers engineers to construct a water tower 146 ft. long, 32 ft. wide and 104 ft. high. This mammoth tower is capable of cooling 18,000 gal. of water a minute from a temperature of 105 to 85 degrees when the outside temperature is 72 degrees and the relative humidity 60. It makes possible the repeated use of the same supply of water with a loss of only 5 per cent due to evaporation. The tower is of substantial type and is capable of withstanding a wind velocity of 90 miles an hour.

Equally remarkable in connection with the power plant is the fact that no coal will be shoveled in and no ashes shoveled out, as everything is to be operated automatically. A car dumps the fuel cargo into a hopper and another car comes along and receives a load of ashes.

Reo Sales Company Wins Appeal in Patent Suit

DETROIT, March 7—The United States Circuit Court of Appeals for the second circuit has handed down a decision in a suit brought by William Barber against the Otis Motor Sales Co. of Utica, N. Y., declaring that the valve gear used in automobiles manufactured by the Reo Motor Car Co. does not infringe the Barber patent. It was also held that the Barber patent itself was invalid. This litigation has been pending since 1915 when Barber brought suit against the Reo distributor in Utica and won the case under such circumstances that he claimed that the decree of the Federal court of that district was also binding upon the home corporation at Lansing, Mich.

Barber's decree was affirmed by the United States Circuit Court of Appeals, but Barber then started suit against the Reo Motor Car Co., Inc., of New York, evidently under the misapprehension that it was the parent company whereas it is only a sales organization. In this case he sought an injunction against the exhibition of Reo cars at the New York automobile show in 1917.

The New York suit was decided against him and the Michigan suit was deferred pending the outcome of the litigation in the east. In view of the apparent conflict between the two Federal courts in New York City, the Court of Appeals sent the Utica case back for a new trial. The new trial was given in January 1918 and on May 20 the Federal Court of Utica again sustained the Barber patent. The defendant again appealed and the decision of the Circuit Court of Appeals in its favor is the result.

U. S. TRUCK GUARANTEES PRICE

CINCINNATI, March 4—The U. S. Motor Truck Co. has guaranteed its prices against decrease until July 1. This announcement was contained in a letter addressed to all distributers, dealers and salesmen. The announced purpose of the company is to do its share in stabilizing the automotive industry.

METAL MARKETS

STEEL producers, with few exceptions, feel very much like the man who prepared a sumptuous feast only to have the guests whom he had bidden to his festive board disappoint him. For weeks and weeks the "independents" had been carving prices in the hope that they would bring out a crush of buyers. When the latter failed to materialize, at least one of the "independents" became sufficiently disturbed to announce an upward revision of prices "to meet those of the U. S. Steel Corporation." For all that, it is admitted in all quarters of the steel industry that further downward readjustment of values is certain to come in due time. It is deplorable, however, that orderly progress in this direction is being retarded by what old-timers in the steel market call the chronic aversion of buyers to placing orders in a declining market. It is quite possible that steel prices will present still more of a crazy quilt in point of variation between the different interests before liquidation in production as well as in values has run its full course. This liquidation, which has not yet been completed in steel, appears to be an accomplished fact in the pig iron market, where output of merchant furnaces is now less than 40 per cent of capacity. In the Middle West, strikes in union foundries are impeding the quickened flow of pig iron from blast furnaces to foundries, but in spite of this untoward factor and the light melt of open shops, an improvement in foundry demand is noted. Inquiry for sheets, perhaps the best barometer of conditions in the automotive industries, is improving very slowly but steadily. There has been much more activity in the market for sheet bars, non-integrated sheet mills that cater to the automotive industries and that depend for their supply of bars upon other mills now being in a position to buy at prices permitting them to compete with more chances of success for sheet business. The aluminum market remains dormant so far.

Pig Iron—Several inquiries for foundry and malleable iron from automotive foundries are in the market. Prices appear to have reached very near bottom. Recent Interstate Commerce Commission decisions, refusing suspension of higher freight rates on ores from certain mining points to Lake Superior ports, make it doubtful whether the generally looked for cut in ore prices can be made such as to lessen iron production costs materially.

Steel—Sheet bars are reported to have been sold at as low as $35. Offers of wire rods at $47 failed to find buyers. So far there has not been sufficient fresh inquiry for cold-rolled strip steel from automotive sources to bring about the establishment of a dependable market level under the changed order of things, but cold-rolled strip steel producers are in a flexible mood of mind, and, when business in worth-while tonnages is once offered, surprisingly low prices will be forthcoming as the result of genuine competition. Sheet prices continue in a state of flux, but sheet mills specializing in highly finished automobile sheets are anxious for orders.

Aluminum—Virgin ingots, 98 to 99 per cent, have been offered in the "outside" market at as low as 23c. The market is decidedly a buyers' affair.

Copper—Strenuous competition has set in between two of the leading interests and, as a result, 12½c. has become merely a basis for cutting under when business offers.

Lead—Following sales at as low as 3.75c., the market strengthened and 4c., New York, is now an inside price. Foreign competition has been eliminated.

FINANCIAL NOTES

Hayes Mfg. Co. reports a loss of $189,328.28 for 1920 in the report as of Dec. 31. This, with other deductions, wiped out the surplus and leaves a deficit of $129,936.54. The company had a surplus of $142,770.33 at the beginning of the year, from which preferred dividends of $59,468 and common dividends of $22,500 were deducted. Current assets Dec. 31 amounted to $1,109,112.25, of which $1,002,920.34 is credited to inventories calculated on market value. Current liabilities total $191,955.40. Accounts payable were $97,-614.61; accounts receivable, $98,541.01, and cash on hand, $10,150.70. Reserve for depreciation was $392,106.68. President H. H. Smith reported the shutting down of the plant had proved disastrous.

Motor Wheel Corp. report as of Dec. 31 shows total assets of $9,629,942.29. Current assets of $4,479,381.74 include inventories on hand and in transit of $2,891,822.48; notes and accounts receivable, less reserve, $868,385.66; Liberty Bonds, at market value, $54,114.85, accrued interest $2,429.87; cash and short-term bankers' acceptances $662,628.88. Current liabilities include accounts payable, $79,785.96; accrued wages, $46,699.47; accrued local taxes, $26,037.01; provision for Federal income and profits tax, $112,035.74.

Michigan Stamping Co. reports sales totalling $4,804,143.56 and profits of $441,456.06 in its annual statement. Total assets are listed at $4,352,881.19 and surplus is $316,974.71. Accounts payable total $159,892.08; accounts receivable, $664,195.64; Government bonds are listed at $172,886, land contracts at $143,487.92 and inventories, $1,346,679.85.

Stromberg Carburetor Co. has passed the quarterly dividend on common stock. The company paid a dividend of 50 cents in the December quarter. Net profits for 1920 operations, after all allowances, were estimated at $410,000, or $5.45 a share, on the 75,000 shares of capital stock outstanding.

Wire Wheel Corp of America reports net sales for 1920 as $3,234,100, as compared with $2,885,474 in 1919. Profits before deductions for patent depreciation and dividends amounted to $485,825, all Federal taxes and other depreciation being deducted. The balance sheet shows a surplus of $1,563,686.

Acason Motor Truck Co. will increase its capital stock $150,000 by the issuance of 8 per cent cumulative preferred stock in denominations of $10 a share. The issue will be disposed of through the company's connections to eliminate brokerage charges.

Atlas Drop Forge Co., Lansing, Mich., reports earnings in 1920 of $364,311.37 and total assets $935,174.07, with current assets $689,215.67. Inventory is given as $86,673.81 and reserves on Federal taxes $131,468.21.

Continental Motors Corp. has passed the quarterly dividend on its common stock due at this time. In the last quarter a dividend of 1 per cent and in the previous three-quarters 2 per cent was paid.

Hendee Mfg. Co. has declared a regular quarterly dividend of 1¾ per cent on preferred stock payable April 1.

BILTWELL LOSS INCREASES

AKRON, March 7—The State Savings & Trust Co. of Akron, and the Merchants National Bank of Massillon, receivers for the Biltwell Tire and Rubber Co. of Barberton, report a net loss of $40,000 in operating expenses since they assumed control of the plant and were named receivers on July 26, 1920.

The net loss covers the period from July 26, 1920, to February 5, 1921. Assets of the company including materials, cash and accounts receivable, total $150,-219.34 and liabilities have increased to $190,504.65. The loss consists principally of contractual obligations for raw materials, and depreciation in inventories, it is stated.

Chandler Sales Gain, Net Profits Fall Off

NEW YORK, March 4—Chandler Motor Car Co. in its report for 1920 shows gross profits of $9,440,000, which compares with $6,650,000 in 1919. Net profits after all deductions amounted to $4,213,000, equivalent to about $15 a share on the 280,000 shares of capital stock. In 1919 profits were $5,652,000, or $26.92 a share on the 210,000 shares then outstanding. The amount reserved for taxes in 1920 is $2,428,250, while the amount written off for inventory depreciation was $736,139. The company also established a loss of $165,702 during the year through the sale of Liberty bonds.

Inventories are carried at $6,524,000 in the general balance sheet as of Dec. 31, 1920, which compares with $4,302,-000 in 1919. Cash on hand increased to $940,000 from $66,541. The profit and loss surplus at the end of the year totaled $5,971,000 as against $7,225,000 in 1919. The latter total was figured before allowance for Federal taxes.

Total sales for the year were $38,757,-501.89, a gain of about $11,000,000 over the $27,866,967.13 total in 1919, said President F. C. Chandler in his remarks to stockholders. Business prospects for 1921 have shown considerable improvement, he said, since Jan. 1.

JORGENSEN POSITION GOOD

WAUPACA, WIS., March 7—Satisfactory reports on the condition of its affairs were made to the stockholders of the Jorgensen Mfg. Co. at its annual meeting. The assets total $266,397, about half of which is in cash and accounts receivable. The total current liabilities are only $20,581, including a mortgage on the property and unpaid dividends. Charles L. Bryden of Berlin, Wis., and E. H. Jones of Weyauwega, Wis., were elected to the board of directors. F. Jorgensen, C. H. Jorgensen and Julius C. Jorgensen, who have conducted the business of the company since it was organized, were unanimously re-elected.

TO LIQUIDATE INTERLOCKING

AKRON, March 10—The receivership for the Interlocking Cord Tire Co., made temporary by the local courts Jan. 17, has been made permanent, and Elihu Harpham, receiver, has been directed by the court to liquidate the affairs of the concern, which has assets not exceeding $150,000 and liabilities, including judgments held by creditors, exceeding $350,000. Talk of the formation of a new company to take over the plant is being indulged in but it was not regarded as serious by the rubber trade here.

Bank Credits

Written exclusively for AUTOMOTIVE INDUSTRIES *by the Guaranty Trust Co., second largest bank in America.*

NEW YORK, March 10—The inauguration of Mr. Harding and the deliberations of the Supreme Council in London last week apparently had no significant effects in financial circles. The foreign exchange market was quiet and steady, with a firmer tone toward the end of the week, while the bond and stock markets declined, but only fractionally. The Stock Exchange on last Saturday experienced the quietest day in nearly seven months. Sales for the day at 146,200 shares compared with 126,160 on Saturday, August 14, 1920.

The money market was also quiet, with call money firm at 7 per cent, and with a range of 6 per cent to 7 per cent. While funds were said to be plentiful in the call market, there were, on the other hand, few offerings in the time market, and transactions were light, with rates unchanged from the week before.

Loans of the New York Associated Banks declined $17,782,000, making a total reduction in loans since October 16 of $515,013,000. Excess reserves over legal requirements at $3,983,650 marked a decline for the week of $10,357,330. Net demand deposits increased $21,-415,000.

The ratio of total reserves to deposits and Federal Reserve note liabilities combined, for the New York Federal Reserve Bank, was the highest since last September. The ratio was 42.2 per cent, as against 40.5 per cent the week before. Total gold reserves increased $24,994,000, and total cash reserves $23,210,000. Total bills on hand declined $29,847,000, total earning assets $27,855,000, and net deposits $9,389,000.

The Federal Reserve banks as a whole continued the steady progress which was interrupted the week before for the first time this year. Re-discounts declined nearly $45,000,000, to the lowest point for the year. Gold reserves increased $22,777,000, while net deposits declined $34,800,000, and Federal Reserve notes in circulation $9,095,000. As a result, the ratio of gold reserves to Federal Reserve notes in circulation, after setting aside 35 per cent against net deposits, increased from 58.1 per cent to 59.3 per cent.

JOHNSON RECEIVER APPOINTED

SOUTH BEND, IND., March 7—The Union Trust Co. has been appointed receiver for the Johnson Motor Wheel Co., which offered no objection to the appointment. The receiver was directed to carry on operations and to work up the inventory now on hand. The company has a total indebtedness of $200,000, most of it bank and merchandise claims. A creditors' committee was appointed in December and decided to accept notes payable Oct. 1, 1921, providing the company would levy an assessment against the stockholders to raise $125,000. This the stockholders refused to do.

Men of the Industry

Robert S. Wilson who has been manager of the truck tire department of the Goodyear Tire & Rubber Co. has been promoted to the position of manager of the western division with headquarters in Chicago. His territory will cover 10 states. Wilson, is a Princeton graduate, joined Goodyear in 1912. His first work was checking inventories. He became manager of the solid tire department in 1917 and with the advent of the pneumatic tire for trucks, his duties were broadened to include the entire truck tire department.

Harry Wilkin Perry has resigned as general manager of the Trailer Manufacturers Association of America. His resignation will become effective as soon as his successor has been appointed. Perry became manager of the Association when it was organized two years ago going there from the National Automobile Chamber of Commerce where he had served for eight years as secretary of the Motor Truck, Good Roads, Export and Legislative committees.

J. P. Matthews is now in active charge of the Midwest Rubber Manufacturers' Association as secretary and general manager. He was for several years general purchasing agent for the Mason Tire & Rubber Co., during the course of which employment he visited the Straits Settlements to investigate the crude rubber situation.

Robert E. Page who recently has been engaged in field organization work for the Hawkeye Truck Co. and the Nelson Motor Truck Co. and who formerly was in the foreign sales organization of Dodge Bros. has been appointed general sales manager of the O'Connell Motor Truck Co. of Chicago. He will undertake at once the building up of a national sales organization for this company.

N. H. Van Sicklen, Jr., vice-president of the Van Sicklen Speedometer Co., will be in charge of the Elgin, Ill., plant, following its absorption by Stewart-Warner. His first assistant will be Edward McDonough. George Underwood, former superintendent, retires. It has been decided to remove the sales office from Elgin to Chicago.

J. M. Dine has been appointed vice-president and general manager of the Oldfield Tire Co. of Akron. He has been identified with the rubber industry for fourteen years, first with Goodyear and then with Firestone. Other officers chosen were B. M. Robinson, secretary; H. L. Allsopp, treasurer, and M. E. Moffett, assistant treasurer.

R. H. Johnston, who has been vice-president of the White Motor Co. with headquarters in Washington, has resigned, to enter the investment banking business in New York. He formerly was manager of the White branch in New York and president of the New York Dealers Assn.

T. W. Van Sickle, for several years sales representative of the New Departure Mfg. Co., has organized the V-S Sales Co., with office at 856 Penobscot Bldg., Detroit. The company will be direct manufacturers' representatives in Detroit and Michigan territory.

W. A. Murfey, sales promotion manager of the Standard Motor Truck Co., will handle sales and service on Standard trucks direct from the factory. A large building at the factory has been set apart to house this department, and an expert mechanical staff will have charge of the work.

Harold W. Slauson, who has been in charge of the motor department of "Leslie's Weekly" for the past nine years, has joined the Kelly-Springfield Tire Co. and is in charge of the engineering service department at the main offices, New York.

W. R. Campbell, who has been acting temporarily as treasurer of the Ford Motor Co. has definitely decided not to serve permanently in that capacity and it is understood he will return to the Canadian plant of which he has been in charge for some time.

Howard W. Maxham has resigned as superintendent of automotive transportation with the American Bosch Magneto Corp. to take charge of the maintenance department at the Amesbury, Mass., plant of Gray & Davis, Inc.

W. H. Holmes, advertising manager of the Packard Motor Car Co., has left that organization and will enter the advertising agency field April 1. His resignation was tendered Monday and became effective immediately.

Archibald Black, of the firm of A. & D. R. Black, consulting engineers, Washington, D. C., has been appointed an aeronautical engineer with the United States air-mail service.

H. A. Longshore, vice-president, and Frank B. Wilson, advertising manager of the Climax Rubber Co., Columbus, have established executive offices in New York at 505 Fifth Avenue.

R. T. Walsh, formerly advertising manager of the King Motor Car Co. and later with the Apex Motor Corp., has joined the organization of the Service Corp. in the Detroit branch.

B. Moss McKenzie has resigned as general purchasing agent of the Ford Motor Co. of Canada. He has not announced the reason for his retirement nor his plans for the future.

W. G. Torrance, formerly with the purchasing department of the Timken-Detroit Axle Co., has taken over the sales end of the Lincoln Steel Products Corp., Detroit.

Hubert E. Hartman, assistant secretary and general attorney for the Ford Motor Co., severs his connection, March 15, to enter business for himself.

L. F. Jollat has been made manager of the Detroit branch of the Miller Rubber Co. Jollát comes to Detroit from Cleveland, where he was with the Goodrich organization.

John H. Samuels has been appointed St. Louis district representative for the Midwest Engine Co. Samuels was formerly with the tractor plant of the Moline Plow Co.

C. J. Welch, assistant general sales manager of the United States Rubber Co., has been elected a director of the company.

W. H. Van Dervoort Succumbs to Illness

MOLINE, ILL., March 7—W. H. Van Dervoort, head of the R. & V. industries in East Moline, died at the family home in Moline, after a year's illness. He was 52 years old and for 22 years had been in partnership with O. J. Root his former classmate, in manufacture of gasoline engines and automobiles.

He was born in Ypsilanti, Mich., Feb. 28, 1869, graduated from the mechanical engineering department of Michigan Agricultural College and took post-graduate work at Cornell. He returned to Michigan as instructor and later went to the University of Illinois as assistant professor of mechanical engineering. In 1899 he quit pedagogy to establish the first factory in Champaign. Two years later the R. & V. plant moved to East Moline where it has since been located.

During the war he was a member of the munitions standard board and of the national war labor conference board. In 1919 he was a member of the board of five sent abroad to study industrial conditions in Europe. He had been president of the Society of Automobile Engineers and a member of the committee on management of the American Motor Car Association, which later became the Automobile Chamber of Commerce.

Dayton Section S. A. E. to Discuss Aviation

DAYTON, OHIO, March 9—The Dayton section of the Society of Automotive Engineers will meet March 22 at the Engineer's Club. Four talks on aviation development will be given. G. M. Williams, general manager of the Dayton Wright Airplane Co. will talk on commercial aviation, covering accomplishments in this line since the armistice.

C. F. Taylor, the engineer in charge of the power plant laboratory at McCook Field, will discuss developments in power plants and in fuels which have made possible flights at high altitudes, increase in compression ratios, and increase in engine size and efficiency.

Propeller construction will be treated by F. W. Caldwell, chief of the propeller branch at McCook Field. Lieut. C. N. Monteith, chief of the airplane section at McCook Field, will speak on aircraft design and performance, paying particular attention to the newer phases of airplane construction.

DETROIT COST CHAPTER FORMED

DETROIT, March 4—Detroit Chapter of the Industrial Cost Association was organized at a meeting attended by a score of officials connected with various Detroit plants held at the Tuller Hotel Wednesday. J. W. Stannard of the American Auto Parts Co. was elected chairman; E. M. Brown of the American Blower Co., vice-chairman; and A. Rae DuBell, secretary-treasurer of the Adams X-Ray Co. was named secretary-treasurer.

Waller Crow, secretary of the Schaffer Engineering & Equipment Co., Pittsburgh, spoke briefly in outlining the aims of the association.

A. A. Alles, Jr., secretary and treasurer of the National Association, told of the steps taken thus far and read a long list of executives who were members.

WOULD FIGHT OHIO BILLS

CLEVELAND, March 5—Ohio automobile interests—producer, distributor and retailer—were urged to unite their activities in a common fight to prevent the automobile and truck being taxed off the highways, at a meeting of the Automotive Association of the Chamber of Commerce.

Calendar

SHOWS

Mar. 12-19—Boston, Annual Automobile Show, Mechanics Bldg. and South Armory.

Mar. 14-19—Omaha, Annual Automobile Show, Omaha Automobile Trade Ass'n, Inc., Omaha Auditorium, C. G. Powell, Mgr.

Mar. 14-19—Washington, Annual Automobile Show, Washington Automobile Dealers' Ass'n, Rudolph Jose, Chmn.

Mar. 19-26—Detroit, Annual Automobile Show, Detroit Automobile Dealers' Ass'n, Morgan-Wright Building.

April 3-9—Denver, Annual Automobile Show, Auditorium.

April 4-9—Seattle, Annual Automobile Show, Seattle Motor Car Dealers' Ass'n, Arena Hippodrome.

FOREIGN SHOWS

Mar. 23-28—Witwatersrand Agricultural Show including machinery and motors sections.

April, 1921—Sofia, Bulgaria, Tractor Trials, under the Bulgarian Ministry of Agriculture.

Apr. 20 - May 5 — Mexico City, Mexican Automobile Show, National Theatre Bldg.

May 28, 1921 — Czecho-Slovak International Automobile Exposition of Cars, Trucks, Tractors, Motorcycles and Equipment. Prague.

May 28-June 8—International Automobile Exhibition, Basle, Switzerland.

June, 1921—Reykjavik, Iceland, Agricultural Exhibition—Agricultural Machinery—Icelander Agricultural Society, Reykjavik, Iceland.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Nov. 4-12 — London, British Motor Show, Society Motor Mfrs. and Traders.

CONVENTIONS

May 4-7 — Cleveland, National Foreign Trade Council.

May 17-19—Buffalo, Convention of Factory Service Managers, Auspices of Service Committee, N. A. C. C.

May 24-28 — West Baden, Ind., Summer Meeting Society of Automotive Engineers, West Baden Springs Hotel.

Oct. 12-14, 1921—Chicago Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

RACES

July 24—Grand Prix, Le Mans.

S. A. E. MEETINGS

Boston section—March 18—Engineers' Club.

Buffalo section—April 19—Paper on "Carbureter Performance," by F. C. Mock.

Dayton section—May 3.

Detroit section—March 25—Discussion of "The Relation Between the Industry and the Department of Engineering Research of the University of Michigan," by Prof. E. A. White. Detroit Board of Commerce.

Metropolitan section—March 16—Paper on "Brakes," by H. G. Farwell. Automobile Club of America.

Metropolitan section—April 14—Paper on "Low Grade Fuel Carburetion," by A. H. Beach.

Minneapolis section — April 6 — Discussion of repair equipment.

Washington section—March 18—Highway and Highway Transport Trading. Cosmos Club.

Washington section—April 1—Aeronautical Engineering Session.

Duesenberg Team Enters for French Grand Prix

PARIS, Feb. 28—(*Special Correspondence*)—By reason of the formal entry to-day of a team of four Duesenberg cars in the French Grand Prix race, on July 25, immense additional interest is given to the French classic. Two of the Duesenbergs will be in the hands of American drivers and two in the hands of Frenchmen, the persons selected, because of their knowledge of local conditions, being Albert Guyot and the amateur driver M. Inghibert. The latter was scheduled to drive a Ballot in the French race, but abandoned this mount in favor of the Duesenberg eight head.

This is the first occasion on which a modern American racing team has lined up in an important European automobile race, and the encounter is looked upon with unusual interest for while the American machines which were sent to Europe fifteen years ago were decidedly inferior, it is admitted that modern American racing cars are capable of holding their own with the best in Europe.

The number of starters in the Grand Prix now stands at 19, as follows: 4 Ballot, 3 Darracq, 2 Sunbeam, 2 Talbot-Darracq, 3 Fiat, 1 Mathis, 4 Duesenberg. There is a possibility of a team of three Italian Itala cars being entered and one each from the Belgian firms of D'Aoust and Abadal.

BRITISH SHOW DATE SET

LONDON, Feb. 25—(*Special Correspondence*)—The Society of Motor Manufacturers and Traders have fixed their car show for the dates Nov. 4 to 12 inclusive. It will be preceded by the French (Paris) show and will be followed in December by the Belgian show. It is not announced whether the British car show will be held at Olympia or, as last time, jointly at Olympia and the White City. A section of the trade would prefer the show to be held solely at the White City rather than in two sections, and there is plenty of space at White City for the complete show.

Mexico Sets Show Date from April 20 to May 5

NEW YORK, March 7—Confirmation that the date of the first automotive exhibition in Mexico City will be April 20 to May 5 has been obtained by EL AUTOMOVIL AMERICANO, the Spanish automotive publication of the Class Journal Co. The show date was originally set to be April 10 to 25 and in an announcement by the Bureau of Foreign and Domestic Commerce the first week in April was given. However, the later date has been finally chosen, as was revealed in the telegram from the show management. Passenger cars, motor trucks, tractors and equipment lines will be exhibited in the new National Theater Building which is being thrown open to the public for the first time. Information from the show management is that practically all of the 45 American cars represented in Mexico City will be exhibited.

AUSTRALIA CUTS WHEEL TAX

OTTAWA, ONT., March 5—Ottawa Trade and Commerce Department is advised that Customs regulations for Australia in regard to motor car wheels have been modified. By the order of the Minister of Trade and Custom there, wheels made expressly for and usable only with motor cars shall be classed for Australian tariff purposes under the item applicable to motor car chassis. The order went into effect Nov. 30. The effect of this order is to reduce the British duty on motor car wheels imported separately or loose, from 40 to 7½ per cent and on Canadian and other wheels from 55 to 17½ per cent ad valorem.

S.A.E. Book New York and Detroit Speakers

NEW YORK, March 7—The Metropolitan Section of the S. A. E. at a meeting on March 16 at the Automobile Club of America will discuss the subject of brakes, H. G. Farwell reading the paper. An invitation is extended to all members of the industry to attend the meeting, which will be preceded by a dinner at the clubhouse at 6.30 p.m.

After the discussion of Farwell's paper, a moving picture film produced by the Bantam Ball Bearing Co. will be shown. This company was among the first to solve its industrial troubles through co-operation between the management and the employees. The success of the company, as a result of this action, which was taken a number of years ago, has caused them to reproduce the episode in the form of motion pictures.

The Detroit Section's guest on March 25 will be Prof. E. A. White, who is at the head of the Department of Engineering Research at the University of Michigan. This department was established to enable the industries to make use of the excellent engineering laboratory facilities of the University and maintain a co-operative connection between manufacturers and technically trained men. This talk will be significant because of the recent decision of the S. A. E. to co-ordinate research work in the automotive industry.

ROTARY TIRE RECEIVER NAMED

ZANESVILLE, OHIO, March 5—Upon the application of Edward O. Sterns and others who are stockholders, B. H. Loveless has been appointed receiver for the Rotary Tire & Rubber Co. C. W. Bryson of Columbus, vice-president of the company, declares that it is solvent and claims that the receivership proceedings were brought in order that certain contracts can be set aside.

AUTOMOTIVE INDUSTRIES
THE AUTOMOBILE

VOL. XLIV NEW YORK—THURSDAY, MARCH 17, 1921 NO. 11

What Is the Average Life of Cars and Trucks?

Analysis of registration, production, export and import figures over a period of years leads to the conclusion that the average life of the 2,000,000 cars retired from service in last 7 years was about 5.3 years

By P. M. Heldt

As highway transportation develops and passenger cars and trucks become practically the sole means of road travel the proportion of first purchasers of cars and trucks in the total of car sales will decrease, and the demand for new cars each year will become more and more nearly equal to the number of cars which drop out of service. For this reason it is becoming increasingly important for the trade to know how many cars will be required for replacement of those withdrawn from service.

If we know the average life of a car or truck it is a simple matter to estimate the number required for replacement in a given year, but it is an easy matter to go astray in efforts to determine the average life.

For instance, one method of reasoning is as follows: "There is no reason why a car should not last indefinitely, because all wearing parts can be replaced, and in case of the breakage of any part, even if it be such an important one as the frame, it is always cheaper to buy a new part and substitute it for the broken one than to buy a new car."

This argument was put forth in a letter recently received from a company which makes a strong point of the fact that the aggregate price of all the parts going into its car is no greater than the price of the complete car. The proposition sounds quite plausible, but in practice things do not work out quite that way. The writer knows personally of a low-priced car that was in service by a salesman for three years, during which time it traveled about 30,000 miles. It was then considered no longer sufficiently reliable for this rather severe class of work and the company owning it disposed of the machine for $85.

For two years more it was used more or less by the new owner, who then found it so unsatisfactory that he bought a new car (of the same make). This car, therefore, if it had been retained in commercial service for its whole life, would have lasted less than 3½ years. This seems a short life, yet the service the car gave was considered quite satisfactory. It must be remembered that the car went out on the road day after day, summer and winter, and that its routes could not be selected according to road conditions, but were determined by business opportunities.

On the other hand, we often hear of cars that have been in service for 10 or 12 years and are still giving excellent service. For instance, a considerable number of Packard "eighteens" are in taxicab service in New York now, and as these cars were manufactured in 1909 and 1910, they are close to 12 years old. This illustrates the point that there is a great difference between the life of the average low-priced car and the average high-priced car. The high-priced car represents a large investment and this alone creates considerable aversion to scrapping it as long as it is at all serviceable. The better grade cars, moreover,

owing to the methods used in manufacturing them, do not acquire, at least to the same extent, that shabby appearance and rattly sound that are characteristic of most of the cheaper cars after several years of use. Furthermore, if the car is of a type that lends itself well to some commercial application, that in itself tends to prolong its life, because obsolescence of outward form and of certain mechanical features does not count against a car in these services nearly as heavily as in private use. Furthermore, a taxicab company can, for example, give the car the greater care needed in its advancing years more economically than the private owner.

Since 1912 AUTOMOTIVE INDUSTRIES has compiled annually statistics showing the number of cars registered in the different states, and the number of cars turned out by our factories has been ascertained by the National Automobile Chamber of Commerce. With these figures and the figures of imports and exports, obtainable from the Department of Commerce, as a basis, it should be an easy matter to approximate very closely the *average* life of all cars that have ceased to be used at a given date.

How Replacements Are Determined

The registrations have increased from year to year and the new cars put in service each year partly make up for cars which drop out of service and partly account for the increase in registrations over the past year. The number of cars newly put in service each year is equal to the American production plus the imports and minus the exports. In the accompanying table the production, exports and imports, and the deduced figure of cars newly put into service, are given for each year from 1905 to 1920. By subtracting from the registrations of one year the registrations of the previous year and subtracting the remainder from the cars newly placed in service during the year, we find the number of cars registered the previous year which were not registered during the current year—in other words those retired from service. For instance, in 1916 there were registered 3,585,000 cars and in 1915 2,480,000 cars. This makes the increase in registrations for the year

$$3{,}585{,}000 - 2{,}480{,}000 = 1{,}105{,}000.$$

In 1916 there entered service in this country 1,503,000 cars, which is

$$1{,}503{,}000 - 1{,}105{,}000 = 398{,}000$$

more than the increase in registrations, hence that number were retired in the course of 1915.

The term "retired" as used above requires an explanation. These cars are not registered any longer but a large proportion are still in existence; their useful life has apparently come to an end, but in an emergency a considerable number of them can become active again. This was well illustrated in 1918 when the increase in registrations over the previous year was greater than the total number of cars produced. This was the last war year, when many people who wanted to buy cars could not get them, owing to the restrictions on automobile manufacture and railroad transportation. Not being able to buy a new car, everybody evidently held on to his old one and—more than that—some of the previously "discarded" machines (including many, no doubt, placed in storage by owners absent during the war) were put in service again and figured in the registrations.

By the above method we can calculate the number of cars that disappeared or were retired for each year since 1912. This has been done and the figures are given in the table. It may here be remarked, parenthetically, that the average life of cars depends not solely upon their durability but also upon their liability to accident. Some cars disappear after a year or two owing to serious collisions, fires, etc. On the whole these accidents probably do not greatly affect the average life, but whatever effect they have is taken account of in the following calculation.

The next step is to calculate from the registration, production and retirement figures the average number of years each car was registered. A distinction is here made between the length of time for which a car is registered and its actual life. This is necessary for the following reason.

During the first year some cars are registered for a whole year and others only for a month or two, because new cars are placed in service throughout the year, and if the end of the registration year is only a month or two off, the car has to be registered for that short period of time and counts as one of the cars registered that year. The active period of life represented by that registration therefore varies from a full year to a month or less, and it is not far wrong to assume that the average period is one-half year. During the last year of registration the car, of course, remains registered for the whole year, unless it should be destroyed by accident and the registration cancelled—which is a rather rare case. Therefore, the probability is that a car that appeared in the registration records for six years had an active life of about five and a half years.

Substantially the same result is arrived at by another method of reasoning. The great majority of the cars are put in service in the spring and are finally withdrawn late in the fall and as they count in the registration lists for both the first and the last year of their lives, although their active life is one-half year less than the number of registration years to their credit.

Cars Withdrawn From Service Each Year

Now let it be assumed that each car has a definite life such that it may be registered during six consecutive years. That is, whether it passes out of use through accident, through wear or through obsolescence, this occurs after it has been registered for six years. Then, since in 1910, for instance, there were placed in service 179,580 new cars, this exact number of cars would be registered for the last time in 1915. All cars placed in service previous to 1910 had already disappeared before 1915 and all placed in service subsequent to 1910 would be registered again in 1916. Therefore, in 1916 the number of registrations would be equal to the number of 1915 registrations, plus the number of cars placed in service for the first time in 1916, minus the number of cars manufactured in 1910. Thus by working backward, that is, by subtracting from the number of cars registered any one year, the number placed in service that year and then subtracting the remainder from the number registered the previous year we find the number of cars scrapped the previous year, and it is then only necessary to find out how many years earlier an equal number of cars were placed in service and add one, to determine the number of yearly registrations to the credit of each car. (One is added because the car is registered both the year it went into service and the year it was withdrawn.) For instance, in 1916 there were registered 3,585,000 cars and trucks and in 1915, 2,480,000 cars and trucks, which gives an increase of 1,105,000. As there were 1,503,000 new cars placed in service in 1916, the number of cars scrapped in 1915 was

$$1{,}503{,}000 - 1{,}105{,}000 = 398{,}000.$$

This figure is nearly midway between the numbers of cars placed in service in 1912 and 1913, which would lead

to the conclusion that the average number of registrations of all the cars was

$$\frac{(1916\text{-}1912) + (1916\text{-}1913)}{2} + 1 = 4\frac{1}{2}$$

The above method of calculation can be applied equally well in actual practice, for, although the number of years that cars in actual use are registered is not a definite figure, the average number of registrations per car is definite. However, taking a single year, as above, gives rather unreliable results. For instance, in 1915 the last cars of the two-door type, with the old style of offset bodies and without lighting and starting equipment were getting along in years, and many cars that might have been used a year or two longer were discarded. Another factor that may have increased the number of retirements that year was that Fords sold for $325 for runabouts and $365 for touring cars, and these low prices may have induced many owners to dispose of their old cars sooner than they would otherwise have done. Other cars also were at the bottom prices during that year.

How True Average Results Are Obtained

This difficulty can be eliminated by taking, instead of a single year, a period of several years. The longer the period the more dependable the result. For instance, if we assume again that all cars have a life sufficient for six annual registrations, then all cars placed in service between 1906 and 1913, inclusive, would be scrapped between 1911 and 1918, inclusive. In this way the retirements are extended over periods of both high and low prices, of general prosperity and depression, of lack of factory capacity and of surplus capacity, and a true average, more or less independent of temporary economic conditions, is obtained.

The first year for which registration figures are obtainable is 1912. However, the number of cars which appear to have been scrapped in 1921 is exceedingly high, which may be due to errors in the compilation of the registration figures—a task which always involves many pitfalls. From 1913 on the number of cars retired annually increased fairly constantly until 1918, as would be expected from the constant increase in production. Hence the writer decided to disregard the result of the compilation of registrations for 1912.

It was shown in the foregoing that if the cars withdrawn any one year have a life of say, six years, then the number of cars withdrawn that year is equal to the number of cars newly placed in service six years earlier. As this relation holds for one year as well as for another, it follows that the number of cars withdrawn during a number of successive years is equal to the number of cars newly placed in service during an equal period of years which preceded the period during which the retirements took place by a time equal to the difference between the years of last and first registrations of each car. The total number of registrations of each car would be one greater than the numerical difference thus obtained.

From 1913 to 1919 inclusive, a seven-year period, there were withdrawn from service a total of 2,089,247 cars. It is now necessary to find an earlier seven-year period during which an equal number of cars were first placed in service, and the interval between these two periods then gives a measure of the average life of the cars, after a certain allowance has been made. This earlier period has to be found by trial and error.

During the seven-year period, 1908-1914, there were newly placed in service 1,942,073 cars. This is slightly less than 2,089,247, the number withdrawn from 1913 to 1919. If the number of cars placed in service during this period had been equal to the number retired during the period 1913-1919, the interval between the year of introduction in service and the year of retirement would have been

1913 (1919) — 1908 (1914) = 5 years,

and the total number of registrations of each car would have been one more, or six. Since the number of cars introduced in service during the 1908-1914 period is slightly less than the number retired from 1913 to 1919, we have to take a later period, which makes the interval

STATISTICS BY USE OF WHICH AVERAGE CAR LIFE IS DETERMINED

Year	No. of Cars Produced in U. S. A.	No. of Cars Exported	No. of Cars Imported	No. of Cars Newly Entered Service	Total No. of Cars in Service	No. of Cars Retired from Service
1905	25,000			24,000		
1906	34,000	2,200	1,295	33,100		
1907	44,000	2,894	1,093	42,200		
1908	65,000	2,164	1,347	64,200		
1909	127,731	3,686	1,645	125,690		
1910	187,000	8,443	1,024	179,580		
1911	210,000	15,807	972	195,165		
1912	378,000	23,720	868	355,148	1,033,000	203,859
1913	485,000	26,889	748	458,859	1,288,000	62,431
1914	569,045	26,000	386	543,431	1,769,000	117,400
1915	892,000	64,000	403	828,400	2,480,000	398,000
1916	1,583,000	81,000	1,037	1,503,000	3,585,000	381,260
1917	1,868,000	80,000	260	1,788,260	4,992,000	8,000
1918	1,153,000	47,000	178	1,106,200	6,106,000	402,656
1919	1,974,000	82,000	1,656	1,893,656	7,597,000	735,500
1920	2,241,000	172,000	1,500	2,070,500	8,932,000	
					Total	2,089,247

measuring the average life of the cars smaller. During the seven-year period, 1909-1915, there were introduced in service 2,706,273 cars, which is very much greater than the number retired during the 1913-1919 period. If the number introduced during the 1909-1915 period had been equal to the number retired during the 1913-1919 period, then each car would have been registered only five times. Since the number of new cars of the 1908-1914 period is much nearer to the number of retirements of the 1913-1919 period than the number of new cars of the 1909-1915 period, it follows that the average number of registrations per car is much nearer to six than to five. The exact average number of registrations per car can be found by interpolation as follows:

Difference between numbers of cars placed in service in the 1909-1915 and the 1908-1914 periods

$$2,706,273 - 1,942,073 = 764,200$$

Difference between cars scrapped in the 1913-1919 period and cars placed in service in the 1909-1915 period

$$2,706,273 - 2,089,247 = 617,026.$$

Dividing the latter difference by the former,

$$617,026 \div 764,200 = 0.81.$$

Actual Average Life 5.3 Years

From the above it is seen that the actual average number of annual registrations was 5.81. As above explained, the average active life of the car is one-half year less than this and is, therefore,

$$5.81 - 0.5 = 5.31 \text{ years.}$$

This was the actual average active life of all the cars that went out of service in the United States from 1913 to 1919 inclusive.

High grade cars will last considerably longer, espe-

Move to Unify All Interests in Hub Standardization Work

Ball and roller bearing makers, wood and metal wheel makers, axle manufacturers and others commercially interested join with S. A. E. representatives in meeting at Detroit for purpose of furthering efforts to standardize front axle hubs. Still hope to formulate standard adaptable to use of either ball or roller bearings thus avoiding possible deadlock.

By J. Edward Schipper

EFFORTS at hub standardization are reaching a point where either definite and satisfactory progress will soon be made, or the situation will reach a deadlock which it may be impossible to break for years. The difficult part of the problem arises from seeming impossibility of securing a standard bore for front axles for trucks which is suitable for both ball and roller bearings. The reason for this lies in the fact that for similar capacities the outside diameters of the ball bearings are greater than those of the roller bearings. This alters so many material dimensions that it is extremely difficult, if at all possible, to arrive at a single standard for both.

Hope has not yet been abandoned on this matter, however, and a special committee of ball and roller bearing men is at work on the proposition at the present time for the purpose of reaching a final decision as to whether or not it is going to be possible to adopt a single standard.

It will be remembered that although the report of the committee on hub standards made at the winter meeting of the S. A. E. was accepted by the Truck Division of the Standards Committee, it failed to pass the Standards Committee as a whole, largely because of the opposition of ball bearing manufacturers who felt that they had not been given an opportunity to present their side of the matter. The report which was presented at that time, failed to include the qualification, that the proposed standard was solely for roller bearing front truck hubs, which the ball bearing manufacturers stated worked an injustice to their side of the business. As a result the matter was turned back to the committee for further consideration.

A meeting was called at the Detroit Athletic Club on March 3 by C. C. Carlton of the Automotive Wood Wheel Manufacturers' Association, at the instance of this association, the Society of Automotive Engineers and the Automotive Metal Wheel Manufacturers' Association. At this meeting, which was attended by an extraordinarily representative list of bearing and axle manufacturers, the fact was brought out that to date the two wheel associations had spent about $20,000 in carrying the standardization work along. The object of Mr. Carlton's meeting was to enlist the support of the bearing and axle manufacturers who are as much or possibly even more interested in the work than the wheel manufacturers. This support is evidently to be given, judging by the attitude taken by representatives of manufacturers at the meeting, with the result that a committee is now at work to carry along the investigation for the purpose of determining whether or not it is possible to arrive at a single standard.

The report of this committee is of utmost importance and is being awaited by wheel, bearing and axle manufacturers with considerable interest. Whether or not this work is to progress smoothly and rapidly, or whether it is to be deadlocked in the same way that ball and roller bearing work has become deadlocked in some of its details in other branches of standardization, will depend in large part upon the report to be made by this committee.

As matters stand at the present time, it is very likely that if it is impossible to arrive at a single standard, an effort will be made by axle and bearing manufacturers interested in roller bearing installations to bring out a standard adapted solely to roller bearing installation, as it seems very possible to do this in a way acceptable to all roller bearing and axle manufacturers, although the dimensions may not be ideal. In fact, it is very possible that these dimensions will never be really standardized, but will be accepted eventually as recommended roller bearing practice. No action is likely to be taken in this respect, however, until a report is secured from the ball and roller bearing committee which indicates whether or not it is going to be possible to arrive at a single standard.

Flange Diameter and Bolt Circle

In the meantime, it is probable that quick action will be taken on the standardization of flange diameters and bolt circles for wood wheel hubs. The wood wheel manufacturers are anxious to have this matter settled at the earliest possible date, as at present they are being compelled to meet small differences in dimensions which have no basis in engineering merit or necessity. A committee has been appointed also to take this matter under consideration and to attempt to have a report ready for the truck division of the Standards Committee at its meeting on March 15. It has been pointed out by the wood wheel manufacturers that they entered this question solely because of their interest in the flange diameter and bolt circles. After they had started this work they found that the metal wheel manufacturers were more vitally concerned with the bore of the hub and the bearing installation, and the standardization work was enlarged to meet all wheel interests. This has been carried along and it seemed, until the objections arose at the winter meeting of the S. A. E., that it was about ready for adoption.

One of the points which has been frequently brought up by critics of the hub standardization work is that it is the first effort of the Society to standardize a design. F. G. Hughes of the New Departure Co., brought forth some arguments at the meeting at the D. A. C., stating that he hesitated to have the S. A. E. standardize a design and,

furthermore, believed it to be impossible to use the load capacity as a basis, because the location of the center of gravity of the truck would have a marked influence on the dynamic stresses to be encountered by the parts. He stated that he believed it was perfectly possible to standardize the flange diameter and bolt circle, but did not believe it desirable to include a form and style of spindle, etc., on account of the great variation in dynamic stresses, due to the shift in center of gravity and other influences.

Cornelius T. Myers, consulting engineer, who has been retained by the wheel interests to carry out the detail work necessary for the formulation of these standards or recommended practices, stated that he had worked with a number of manufacturers and committees on this subject and found that they all believed it possible to standardize as far as roller bearings are concerned because of the immaterial differences in practice which exist. Regarding the question of bearing spacing in these front hubs, he stated that no engineering reason existed for the infinitesimal differences which prevail.

Myers said further that the subject of bearings was actively canvassed and studied for five months and it was the unanimous opinion of the sub-committee of five and of the Truck Division of the S. A. E. Standards Committee that ball bearings could not be made interchangeable in any series of hubs which could be laid down because there are fundamental differences in the design of ball and roller bearings which call for differences in dimensions which cannot be composed. To quote Myers further: "The decision of these men to offer as the first step in the standardization program a series of hubs equipped with roller bearings was based on the fact that in the past two years some 95 per cent of the bearings used in the front hubs of motor trucks having load capacities of from 1½ to 7½ tons were roller bearings. All the prominent axle companies agreed that the designs submitted were in line with the best practice and should be followed in new construction. Four roller bearing companies can furnish interchangeable bearings for the proposed standard hubs. The bearings selected are cheaper than bearings now being used on well-designed axles for similar load capacities. The bearings selected are those which will be in quantity production by the roller bearing manufacturers.

"The subject of a standard series of hubs to take ball bearings should be considered by itself and submitted to the S. A. E. when all particulars with regard to it are thoroughly discussed and approved, not only by bearing manufacturers but by manufacturers of axles and of motor trucks."

Myers gave it as his opinion that the success of the proposed standard would depend upon the favor with which it was received by the motor truck trade and not upon the individual preferences of any class of parts manufacturers. "If the proposed standards for roller bearing hubs appeal to the motor truck trade, parts manufacturers will certainly cater to this demand. If the motor truck trade is willing to pay 15 or 20 per cent more for roller bearings, hubs and wheels in order to adopt standards where ball bearings can be installed in hubs of the same dimensions, this is a matter for the motor truck trade to decide. Ball bearings would not be strictly interchangeable with roller bearings in any event, but the suggested type would allow axle manufacturers to machine the same hub castings by means of different tool equipment to take whatever type of bearing the customer wished.

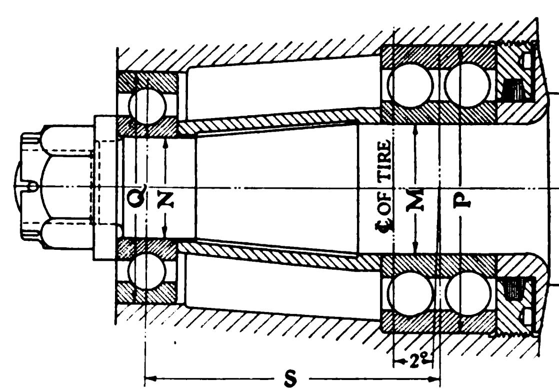
"It is my opinion that the program already approved by the Truck Division of the S. A. E. Standards Committee should be given formal sanction so that 95 per cent of the motor truck trade would be able to take advantage of it, and that work should be carried on to place a similar series of hubs for use with ball bearings before the industry at the earliest possible moment; that to delay the adoption of the roller bearing series in the hopes of getting a really serviceable interchangeability with the ball bearing series would tend to continue the present condition of affairs in many new designs which are at present projected, namely, a multitude of small and unessential variations in design details, the sum total of which constitute a very considerable burden on the truck industry."

T. V. Buckwalter of the Timken Company, urged the adoption of a standard on an economic basis. He stated that it is more a problem of economics than of engineering. He said further that the static loads were the only basis which it was possible to use in making the design and that variations in center of gravity, etc., if they were exceptional, would have to be taken care of by special design anyway.

Discussions of this kind occupied most of the day at the D. A. C. meeting. It was quite apparent that the general trend of opinion at the meeting was favorable to adoption of some form of standard or recommended practice, and if possible, a single standard for both the ball and roller bearings. There were a considerable number, however, who believed that the insistence on a single standard would deadlock the proposition in such a way that nothing would ever be accomplished.

F. W. Gurney of the Gurney Ball Bearing Co., stated in his belief it was by no means impossible to work out a single standard for the two types of bearings and asked that time to give this matter fair consideration be granted the committee, of which he is a member. This was agreed to by all present.

Previous to this meeting at the D. A. C., the ball bearing interests had called a meeting of their own and had drawn up a set of suggested standards for ball bearing front hubs to be incorporated in the report to be made to the Standards Committee, so that in any event, both ball and roller bearings would be given consideration in this work. The proposals they make are incorporated in part in the table and cut given herewith. No action, however, will be taken on these ball bearing front hub dimensions until it is determined whether or not it is going to be possible to arrive at the single standard. The drawings of the ball bearing



Suggested standards for ball-bearing front axle hubs, proposed by representatives of the ball-bearing manufacturers. Not yet adopted or acted upon

front hub suggested for standardization were exhibited at the meeting at the D. A. C.

F. W. Gurney, in his discussion of the possibilities of the single standard, stated that he believed a single standard could be worked out which would incorporate many of the dimensions which were approved for roller bearing practice. The difference which would exist between these and the proposed single dimensions would, of course, be concerned with the larger diameter necessary for equal capacities. Some discussion as to differences in fit between the outer cage of the ball and roller bearing was brought forward, but it was pointed out that this was rather a question of tolerance than dimensions, as there was no idea of so manufacturing hubs that interchangeability would exist between the ball and roller bearing hubs; that is, there would be no intention of sending out a hub originally equipped with roller bearings and then changing it to ball bearings after it had been in service, or vice versa. Consequently, tolerances allowed in manufacture would take care of the question of fit.

The economic side of this hub standardization work is of such importance that it forms one of the most interesting pieces of attempted standardization which has come before the automotive industry in years. It is one of the matters which an impartial observer realizes will be of value to all branches of the industry, but at the same time, there are some knotty problems involved in arriving at a standard or recommended practice which will be fair to all. One is reminded of the discussion on tire sizes which was carried on through the S. A. E. for years and finally settled by the War Industries Board during the war. A single act of this board, which had the authority, was able to settle a question which had been one of the moot points in the tire business for years. Many of the discussions which centered around the adoption of the bell housing for automobile engines are also called to mind.

There is no question but that a standard is much needed and if it is going to be possible to arrive at a single standard for both the ball and roller bearings, an almost ideal situation will have been created. If it is impossible, however, it would be far better to have even five ball bearing standards and five roller bearing hub standards for trucks, giving a total of ten, than to continue the sixty or more which are commonly manufactured at the present time.

What Is the Average Life of Cars and Trucks?

(*Continued from page* 591)

cially if their annual mileage is not very great and if they are carefully driven. On the other hand, the average low priced car does not last as long, particularly if used in arduous commercial service, as by salesmen, physicians, liverymen, etc. One reason why the average is rather low is that the high-priced cars, which in a general way last longer than the low-priced machines, are greatly in the minority. For instance, suppose that a taxi concern operates two makes of cabs, 10 cabs of one make having an average life of four years and one cab of the highest grade of construction having a life of 12 years. Then the average life of the two makes of cab is

$$\frac{4+12}{2} = 8 \text{ years}$$

but the average life of the 11 cabs is only

$$\frac{(10 \times 4) + 12}{11} = 4.73 \text{ years.}$$

It is to this latter figure that the value of 5.31 years for the average active life of all cars corresponds. That is, the short-lived cars are in the majority and they pull down the average in proportion to their numerical strength.

The average life deduced above covers, of course, both passenger cars and commercial vehicles. There is no means of determining the lives of the two classes separately, as in many states no distinction is made in the registrations. As the quality of design and workmanship varies as widely as in passenger cars, there is probably as wide a range in useful life in the one class as in the other.

Since the foregoing computations are based largely upon registration figures, the accuracy of these figures may be questioned. We make no claim of absolute accuracy, but the registration figures we have compiled are probably more representative of the use of automotive vehicles than any other compilation. A statistical company often employed by banking concerns recently estimated that there are 600,000 cars in use in this country that are not registered. This estimate appears to be too high, even after reading the full report of the investigations upon which this company based its estimate. There is, however, a considerable number of cars in use and not registered. Laws such as those governing the registration of automotive vehicles are easily evaded by persons willing to take the risk and necessary trouble to avoid paying the fees imposed and thus save a few dollars. To offset this, however, there are the cars which are twice registered. The commissioner in charge of registration in New Jersey estimated that 15,000 of the cars registered in that State also are registered in other states. This is true of several of the states which have a heavy summer and winter resort business and in states in which trucks and cars are normally used much in two or more states. These and other features of registration probably balance each other in a sense and leave registration figures the best basis upon which to calculate, even if they are not a strictly accurate guide to the number of cars in actual use in the country.

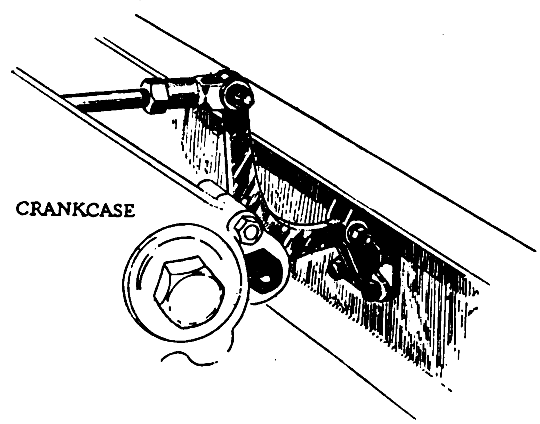
THE original four-cylinder Stearns tractor engine was made in two sizes, 4¾ x 6 in. and 5 x 6 in. Recently a smaller size has been added which can be furnished in three sets of cylinder dimensions, namely, 4 x 6, 4¼ x 6 and 4½ x 6 in. A total of 51 parts are interchangeable on all five models. The new engine is built much lighter than the earlier model and is furnished with an aluminum crankcase for trucks and light tractors. The valve cover is also of aluminum. Electric starting and lighting equipment is optional with this model, the engine being designed with mountings for the starter and generator. Either three-point or four-point suspension can be provided and the size of bell housing is optional. The larger engine is now furnished with a gear drive for the fan and generator, provision being made for mounting a generator by the S. A. E. standard flange mounting. This fan and generator drive goes onto the gear cover of the regular model and is interchangeable with the regular cover.

Mechanical Features of the Rolls-Royce Chassis

Many refinements embodied to increase convenience or add to durability. Slotted skirt aluminum pistons, constant acceleration cams, vibration damper, adjustable governor, hand primer, dual brake drums, special brake adjusting devices, and rivetless frame are among the unusual features. Hand fitting and careful inspection characterize manufacture.

By P. M. Heldt

THIS article has been prepared after the writer had visited the plant of the Rolls-Royce Co. of America, Inc., and was given an opportunity to study the chassis while the parts are in process of construction and assembly. The chassis has been manufactured in England continuously for the last 17 years, and the American product is identical to the British, not only in design, but in method of construction. In fact, the duplication is so exact that a well-known American engineer who is thoroughly familiar with American production machinery and methods, when given an opportunity to inspect in detail two chassis, one American and one English built, placed side by side, was unable to detect any difference definitely indicating which was which.

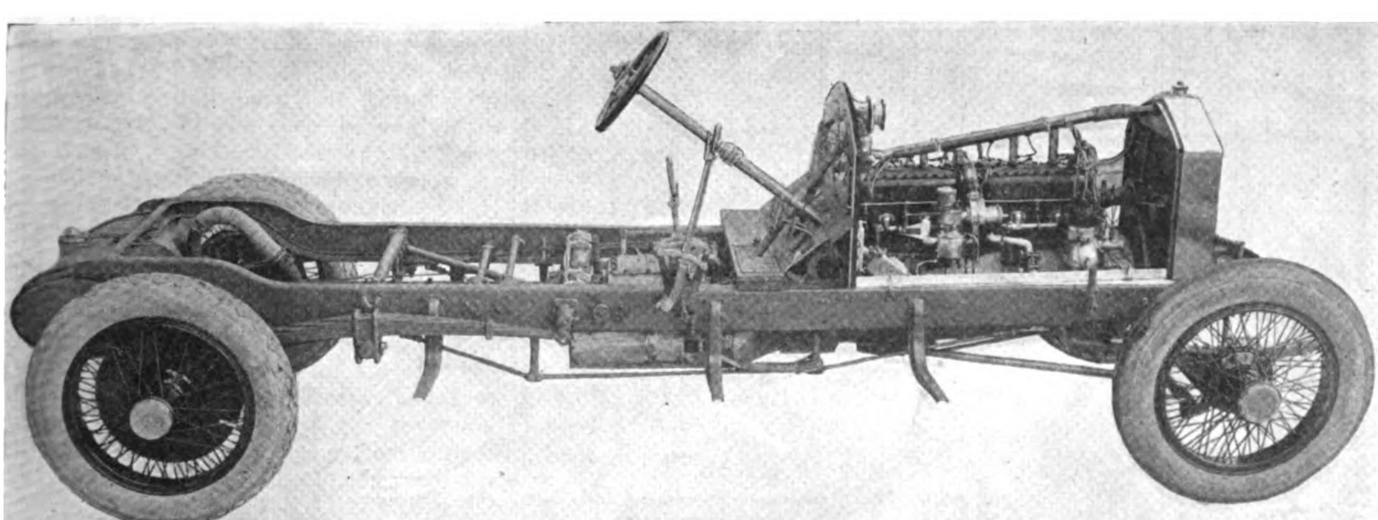


Front engine bracket

Our purpose is primarily to describe some features of the chassis and details of construction which are different or more elaborate than usual. Since the chassis is one of the highest priced of any produced either in this country or in Europe, it is natural to expect the use of the highest grades of material and workmanship, as well as elaborateness of design in respect to those features tending toward the greater comfort and convenience of owner and operator, and longer life of the car.

The engine has six cylinders, 4½ by 4¾ in., cast in two blocks of three, and with a seven-bearing crankshaft of 2¼ in. diameter. The crankshaft is forged from nickel chrome steel and is finished all over, and the bearings are lapped after being ground, to obtain a smoother surface than is possible to obtain by grinding. The crankshaft is, of course, heat-treated, and it is noteworthy that the heat treatment is applied only after most of the surplus stock has been removed, in order to ensure more rapid and uniform cooling on quenching.

The bearing caps in the crankcase are made of nickel steel, heat-treated, and are held in place by means of bolts, rather than studs screwed into the aluminum. For boring out the main bearings in the crankcase, dummy aluminum caps are made use of. The steel caps are ground. The bronze-back, babbit-lined bushings are ground on the outside and are fitted into the crankcase and the bearing cap with bluing to



The Rolls-Royce chassis

insure a perfect seat, so that the joint will stand an oil pressure of 20 lb. per sq. in. Solid bronze liners are placed between the two halves of the bearing, white metalled on the side toward the shaft. Adjustment for wear of the bearings is made by filing down the liners

The engine is supported on the frame by a flexible four-point support on which the Rolls-Royce firm holds a patent. The forward end of the crankcase rests on two bell cranks, one arm of each of which is connected to a frame bracket and the other two arms of which are connected by a tie rod (see sketch). The fulcrum of the bell cranks is on the crankcase. This construction protects the crankcase against stresses due to frame distortion.

Aluminum alloy pistons are used. Trouble from slap and seizing is prevented by slitting the skirt longitudinally on the pressure sides at a slight angle, and circumferentially at the bottom of the ring belt. The four piston rings have an unusual section, being 3/32 in. wide and .137 in. deep. This gives a very large wearing surface at the sides of the ring and evidently is intended to obviate the trouble of rapid wear of the ring grooves sometimes experienced with aluminum pistons. The rings, moreover, are "pinned" so they cannot creep in their grooves, the pins consisting of bolts through the piston wall, with nuts on the inside of the piston, the threaded portion of the bolt being split and spread apart to prevent the nut coming loose.

The cylinders are ground, but in order to obtain a better surface than can be obtained by grinding the cylinders are lapped in with a dummy piston. The valves are made of chrome (rustless) steel and the valve springs of chrome-vanadium steel. Rolls-Royce use the constant acceleration cam which has a concave flank, and in order to grind these cams (which requires the use of a grinding wheel of very small diameter) they had to develop their own grinding machine. Rocker levers carrying the cam rollers are interposed between the cams and the push rods to prevent side thrust on the pushrods. The rocker levers are pivoted on plates bolted to the side of the crankcase and are made from nickel steel, machined all over and hardened. The cam roller is mounted in a yoke on the lever. The roller pin is hollow and has a lug formed on it which fits into a slot on the lever, so that the pin cannot turn. A rivet through the pin fixes it endwise. Unlike the great majority of present-day engines the Rolls-Royce does not have the valve springs and adjusting mechanism inclosed, evidently because inclosure would interfere with adjustment of the valve clearance. Noiseless operation of the valves has been insured by making the valve parts as light as possible and by carefully shaping contour of the cam.

The engine is fitted with a vibration damper designed to eliminate torsional vibration of the crankshaft. This is in the form of a friction-retained flywheel at the forward end of the crankshaft. In addition, the timing gear pinion is mounted on the crankshaft in such a way that driving force is transmitted to it through coiled springs. There are eight of these springs, located between four integral keys in the bore of the pinion and four similar keys on the outside of the driving member. A frictional vibration dampener is also provided to prevent the pinion from oscillating rapidly between the springs. This timing gear drive is claimed to reduce noise and wear throughout the engine.

Connecting-rods are machined all over and are held to very close weight limits. The connecting-rod bolts are made hollow for lightness and are made with an integral lug which fits into a recess in the rod to prevent the bolt from turning. Oil is supplied to the floating bronze bushing at the upper end of the rod through a small tube extending up the shank of the rod.

A carbureter of Rolls-Royce design is fitted. This is of the double-nozzle type and has a piston type of throttle valve. At idling and low speeds only one nozzle is operative. An automatic air valve is fitted which not only controls the amount of air admitted to the car-

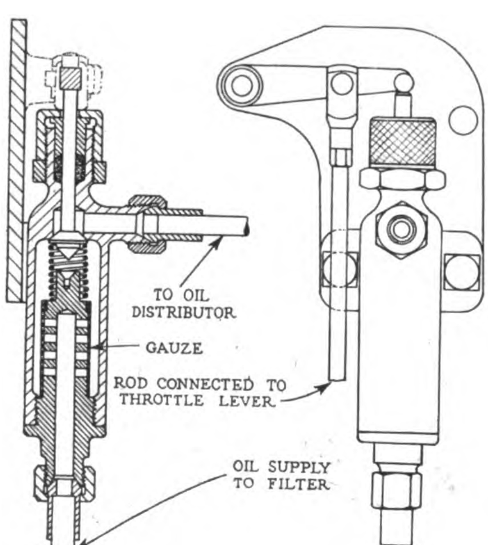


Fig. 1—Oil valve and filter

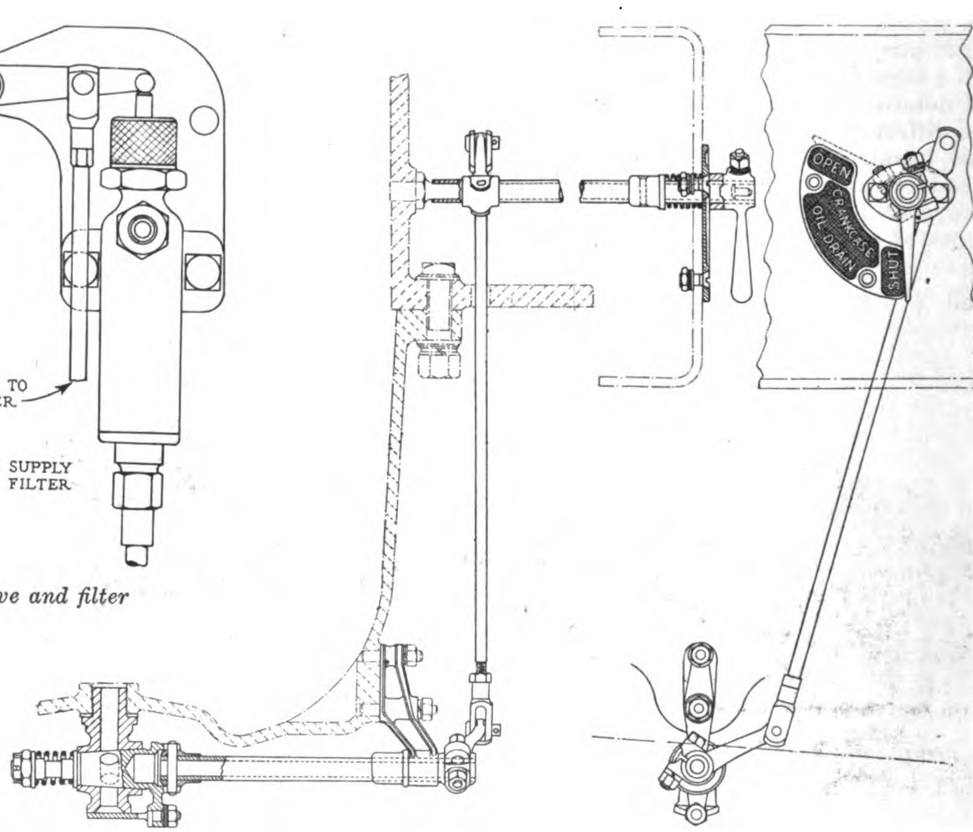

Fig. 2—Oil cock and actuating arrangement

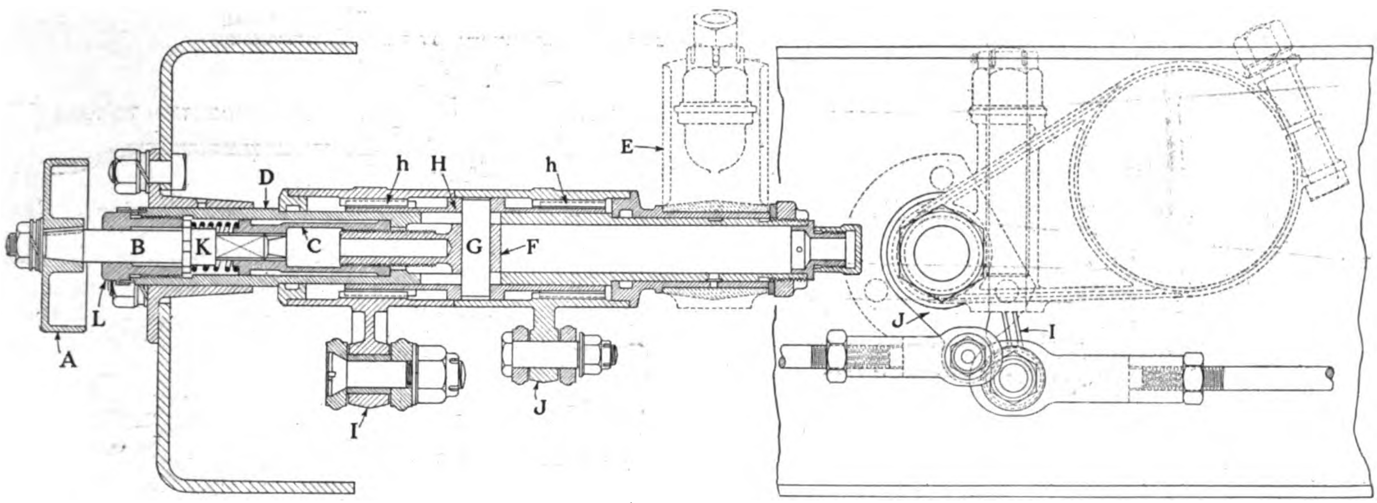


Arrangement of foot brake adjusting device

bureter, but also the vacuum, and, therefore, the cutting-in point of the high speed nozzle. Both nozzles are provided with needle valve adjustment, these valves being controllable (through a small range) from the driver's seat. The air entering the carbureter around the high speed nozzle is drawn through a heater.

The oil pump is of the gear type and has the pressure relief valve formed integral with it. It is driven through a square tube which opens up in case the pump becomes jammed by foreign matter, thus forming a safety link in the drive. The water pump, of the usual centrifugal type, has the peculiarity that water enters the casing from both sides, so that all end thrust is eliminated. It is driven through a universal joint somewhat similar in form to a Hookham joint, the central member being a fiber block. Fuel feed is by air pressure, and the air pump for this purpose is mounted on the governor casing and driven from the governor shaft. This pump is so designed that the pressure is automatically limited to 2-lb. p. sq. in., so that no relief valve is required. Such relief valves are said to be a frequent cause of air leaks.

A governor on passenger car engines is a rarity, but the Rolls-Royce is fitted with one. It acts on the throttle valve and is under the control of a lever on the steering column. When the accelerator pedal is depressed the action of the governor ceases. The advantages claimed for the use of a governor are as follows: In coasting down hill, if the governor is set to say 10 m.p.h., it will hold the throttle closed as long as the car exceeds this speed, and thus save fuel. When driving in traffic the engine can be allowed to idle at a very low speed, for the governor will open the throttle immediately the clutch is engaged and keep the engine from stalling. In gear changing, especially changing down, the governor is useful in getting the speed at which the engine should run when the clutch is disengaged.

The fan consists of sheet aluminum blades bolted to a steel center.

Engine lubrication is entirely by force feed, the pressure being maintained between 3 and 20 lb. Under normal conditions the cylinders are oiled by the spray from the crankshaft, but when the throttle is more than two-thirds opened by the accelerator pedal, an oil valve controlling a direct feed from the pressure system to the cylinders (Fig. 1) is automatically opened by the accelerator, and the cylinders then receive an extra supply of oil. There is a filter within this valve, which prevents foreign matter from getting to the cylinders. An oil level cock in the oil sump is operated by a lever on the left side of the frame (Fig. 2). This cock is fitted with a cover which prevents dirt from entering and stopping up the tap, and this cover is connected to and moves with the tap. A reserve oil tank, with a capacity of 1⅝ gal., is secured to the left side of the frame, and oil can be transferred from this tank into the crankcase by opening the cock at the bottom of the tank. In cold weather, if the oil is very viscous, pressure can be applied to force it from the tank to the crankcase by connecting a tire pump to the top of the tank. The oil pipes are of copper and the fittings are brazed, making a very secure job.

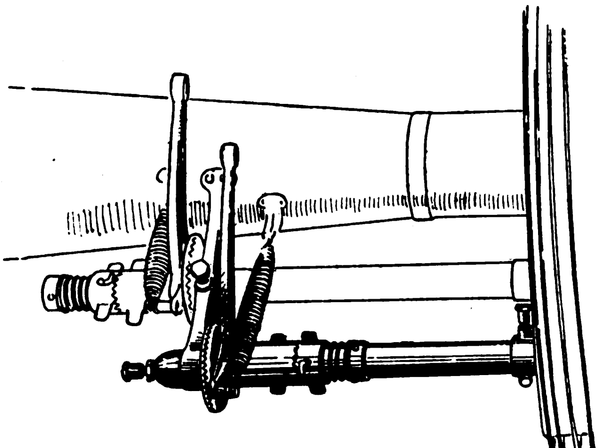
Two entirely separate systems of ignition are provided, one a Watford high tension magneto and the other a battery system made by the Rolls-Royce firm. Both are controlled by a compound switch located at the base of the steering column and operated by a knurled nut at the center of the steering wheel. There are four positions to this switch, namely, magneto alone, battery system alone, both together and all off. In circuit with the coil of the battery system is a ballast coil which tends to keep down the current flow at low engine speeds and also prevents injury to the coil in case the engine should stall and the operator forget to open the switch.

To eliminate chatter in the magneto drive, a small spring-loaded brake is provided, which clasps a ground drum on the magneto, thus introducing a slight countertorque. This makes the drive silent and reduces wear of the universal joints.

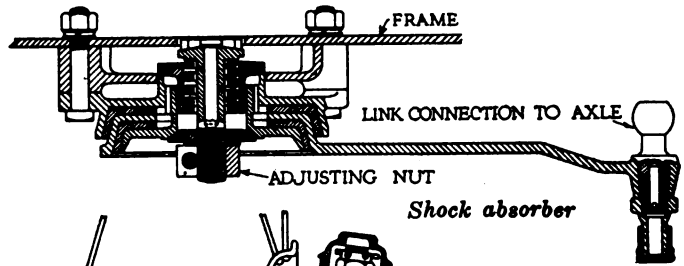
The radiator is of the true cellular type and has nickel silver (German silver) top tank and side plates. It is supported by two ball joints on a cross member of the frame and stayed by a bowed steel strip from the top to the engine. The engine bonnet is of aluminum and is provided with a double hinge at each joint.

In order to facilitate starting and reduce the drain on the battery in cold weather, an engine primer is fitted. A U-tube is connected to the bottom of the carbureter float chamber and fills with gasoline from the float chamber through a check valve, to the level of the gasoline in the float chamber. One side of this U-tube is connected to a hand air pump on the dash and the other to a spraying nozzle in the inlet manifold. The air pump is given a few strokes, whereby a measured quantity of gasoline, together with a certain amount of air, is injected into the inlet manifold through the nozzle, the fuel being thoroughly sprayed and intermingled with the air. Although an electric starter is fitted, a hand starting crank is permanently fixed in place, being held by a leather socket.

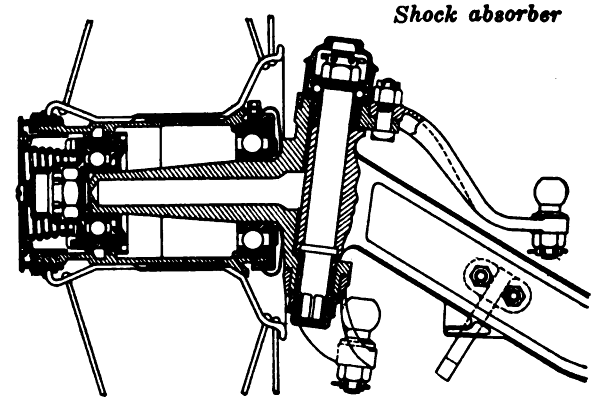
The flywheel is secured to the flange on the crankshaft



Devices for adjustment of rear brakes



Shock absorber



Section of front hub and steering knuckle

by means of tapered bolts and rivets fitted into tapered holes. The clutch is of the reversed cone type and has a lining of friction material which is secured to the clutch cone by means of staples, said to make a much more secure fastening than rivets. Provisions are made for lubricating the clutch pilot bearing from the engine lubricating systems. The center hole through the crankshaft extends through the clutch pilot and at the end of the pilot there is a valve, which is automatically opened when the clutch is thrown out, remaining open as long as the clutch is out. In order that too much oil may not get through to the clutch pilot during this period, the oil is required to pass through a cotton wad. The clutch facing is always steeped in oil. A clutch brake in the form of a spring-controlled fiber pad is provided and presses against a special ring secured to the clutch cone. The position of the fiber pad and the spring lead can be adjusted.

The four-speed transmission is of the selective sliding gear type, and has quite a number of special features. In the first place, the gearcase is cast in a single piece, of aluminum, and has a three-point support upon the frame. Helical constant mesh gears are used to eliminate noise. The first drive shaft, carrying the constant mesh pinion and the direct drive clutch, is mounted between two large ball bearings. The second secondary shaft is mounted on three ball bearings, giving a very rigid support to same and tending toward silent operation of the gears. The driving shaft is also supported in three bearings, a plain pilot bearing in the end of the first mentioned shaft, and two ball bearings, one of which is in the partition wall in the case, which also carries the central bearing of the secondary shaft. The transmission is lubricated with oil of the same viscosity as a good grade of steam cylinder oil and proper provision is made for preventing leakage of oil from the case.

The rear axle is a full floating design, with a housing built up of forgings comprising large diameter flared tubes. The parts are assembled by means of a large number of square-headed bolts. The final drive is by helical bevel gear, with a reduction ratio of 3¼ to 1. The differential gear is of the spur type, and the side gears are forged integral with the axle shafts. Lubrication of the axle is by oil of the same viscosity as that used in the transmission, provision having been made for retaining it in the axle housing. The bevel gear as well as the pinion can be adjusted to secure a proper mesh.

Thrust and torque reaction are taken on a torque tube with a spherical joint at the forward end. In order to locate the two bearings on the bevel pinion shaft as far apart as possible, and thus reduce the lead on the bearing directly back of the pinion, the torque tube is made in two parts joined end to end, and one bearing on the pinion shaft is placed near this joint. The propeller shaft itself is also made in two parts, with a universal joint of the spur and internal gear type between them.

The propeller shaft universal joint is of the ring type. The ring is made in the form of two half rings, and in order to relieve the clamping belts of shearing strains, the surfaces of the joint are serrated. The pins of the joint are tapered and are fitted with hardened steel sleeves which bear in bronze bushes fitted into the ring. Oil lubrication is used for the universal joint, the pins being drilled out so that centrifugal force will carry the oil to the bearing surfaces.

An important feature in connection with the universal joint is the large hollow steel sphere in which it is inclosed. This is made of two drop forgings bolted together, the whole being bolted rigidly to the frame. On the outside of this steel ball is a large spherical bronze socket which forms the front end of the torque tube. Both ball and socket are ground to a close limit of accuracy.

Both sets of brakes act directly on the rear wheels, but there is a separate drum for each, the drums being made of hydraulic forgings. The inner brake is the hand or emergency brake and the shoes are fitted with cast iron liners, while the foot or service brake is the outer one and is lined with Ferodo brake lining. The foot brakes are unusually large, the drums being 17.1 in. in diameter. These drums are provided with cooling flanges ¾ in. deep, cut from the solid, and it is stated that this brake can be applied for long periods without overheating.

All brackets and levers of the brake mechanism are made of drop forged steel, heat-treated. Both sets of brakes are provided with brake equalizers of the differential gear type, neatly inclosed in aluminum housings mounted on cross tubes on the frame.

The foot brake adjustment is, perhaps, the handiest device of the kind ever put on a car (though by no means the simplest) and is covered by a patent. All the operator has to do to adjust the brake is to turn a small handwheel at the side of the frame, the adjustment being self-locking. A sectional view of this mechanism is shown herewith. The handwheel A has the end of its stem B squared to engage with the cap nut C supported

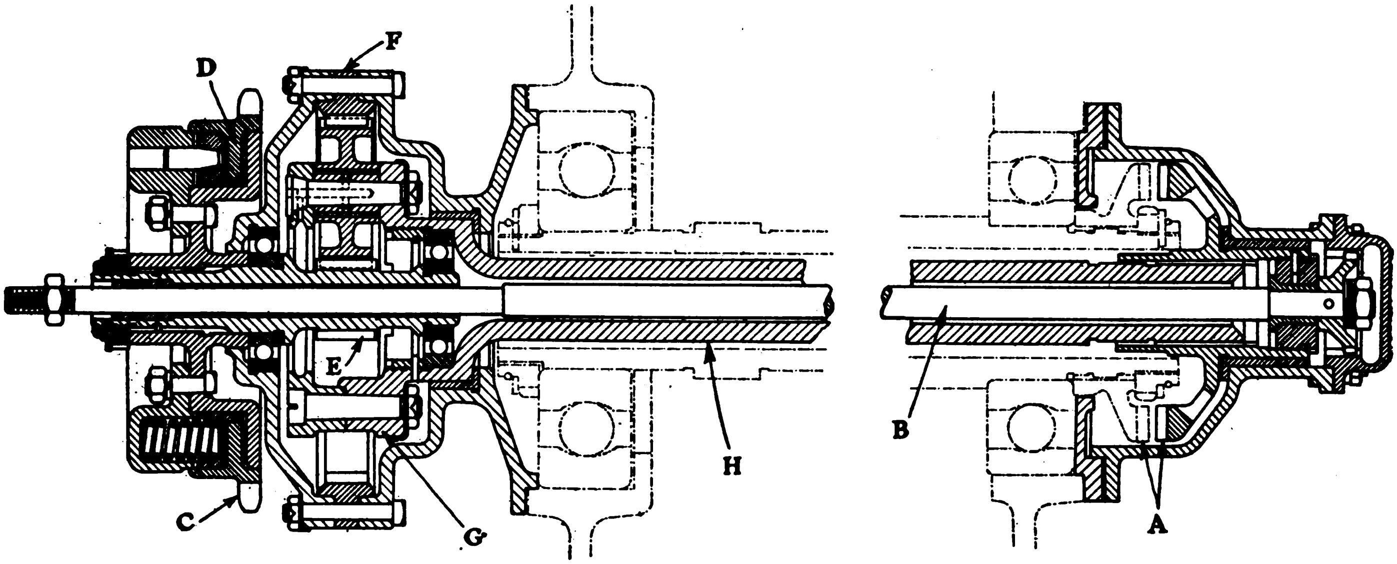


Fig. 3—Arrangement of epicyclic starter gear on secondary transmission shaft

in the tubular member D, which extends between the frame side bar and a bracket E fixed to a tubular cross member of the frame. When nut C is turned by means of handwheel A it draws screw F toward the frame side member. This screw is held from rotating by a pin G extending through slots in tubular member D parallel to the axis thereof, and the ends of the pin extend into holes in the tubular sliding member H, which has steep pitch screw threads of opposite hand cut on it at its opposite ends (h,h). These screw threads engage with similar female threads in the hubs of lever arms I and J, one of which connects to the brake pedal and the other to the brake shaft at the rear axle. Thus when handwheel is turned, tubular sliding member H is pulled through the hubs of levers I and J, causing these levers to turn through slight angles in opposite directions, thereby effecting the adjustment. Ratchet K, which slides along the squared portion of the stem of handwheel A and engages with a corresponding ratchet on the end of hub L, under the pressure of spring M, locks the adjustment.

In addition to this adjustment there are adjustments at the rear axle for both the service and emergency brakes. These, too, are of a very handy type and are illustrated by the sketch herewith. The hub of the lever on the rear brake shaft is made of large diameter and provided with serrations on one side which engage with similar serrations on a dummy hub fast on the shaft. A nut on the shaft screws the two hubs together, thus holding the two serrated surfaces in engagement. The nut itself is provided with coarse radial serrations on its outer face with which engages a sliding locking collar mounted on a key on the shaft. This collar is pressed in the direction of the nut by a coiled spring. When it is desired to make an adjustment, the locking collar is forced away from the nut against the light spring, and slightly twisted around so it will be held in the disengaged position by a pin fastened in the shaft, which extends through a slot in the collar running axially to allow of the motion and circumferentially to effect the locking.

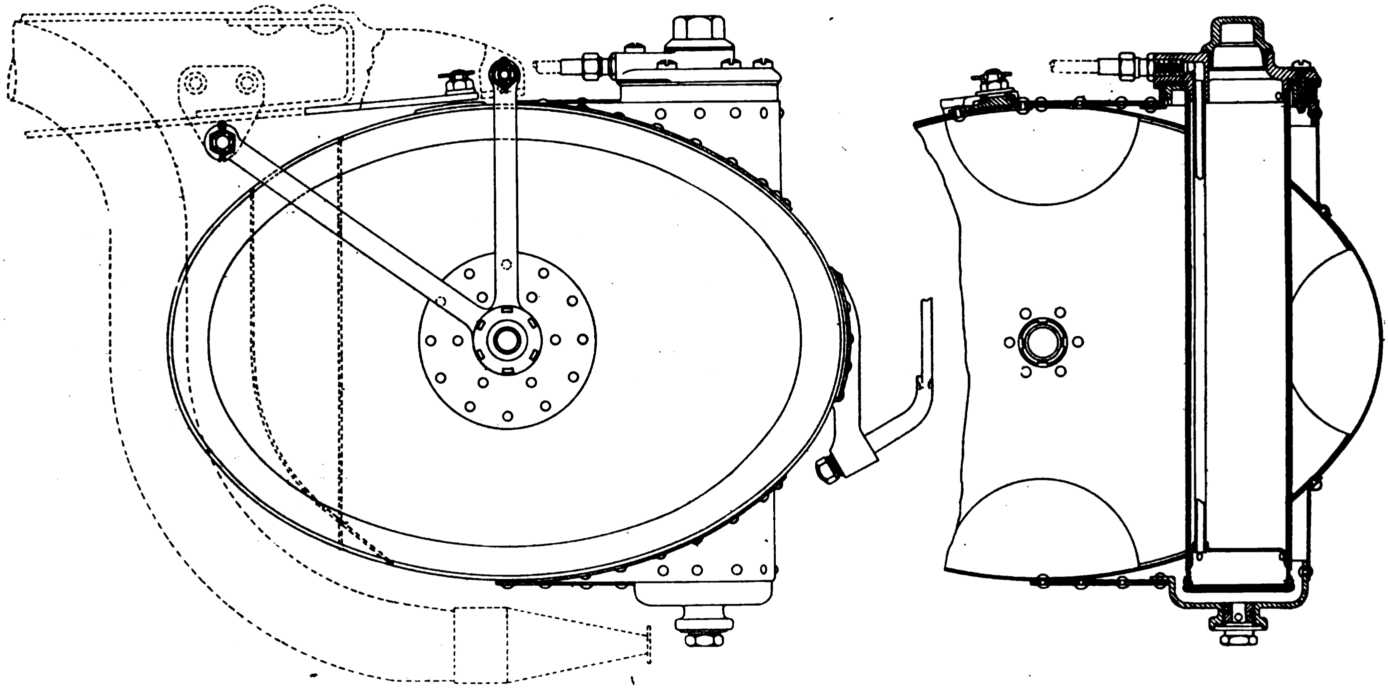
Wire wheels are used, and though these are made by the Dunlop company, they embody Rolls-Royce inner and outer hubs. A serrated drive is used, embodying a large number of teeth and large driving surfaces, with conical supports for both ends of the wheel hub to prevent wobbling. The retaining nuts are positively locked and cannot back off while running. Both hubs are made of pressed steel and are turned down to very light sections.

The mud pan is made of aluminum and is provided with louvres so as to increase the circulation of air through the radiator and prevent the heat and gases from the engine getting into the driver's compartment. This pan extends the whole length of the engine and transmission.

Steering is by a screw and nut mechanism, the nut being split in halves lengthwise, to permit of fitting it accurately to the screw and of making adjustment for wear when required. The nut operates a rocking lever to which the steering arm is secured. This rocking lever is mounted on ball bearings and the steering arm is secured to the rocking lever by means of tapering serrated hubs, these serrations being formed by a process worked out in the Rolls-Royce plant. A feature of the steering gear is that the bearings supporting the worm shaft are located very far apart, whereby the load on the bearing close to the worm is reduced. The ball journal and thrust bearing are located halfway up the column. The control levers are pivoted on brackets brazed to the operating tubes. These brackets can be rotated by disengaging the lever from serrations on the quadrant, as the lever fits into a slot in the bracket. A small spring and plunger keep the lever in contact with the serrations. The control linkage is very carefully made, yoked fittings being used almost exclusively, and when a car passes inspection there is absolutely no play in these connections. Leather boots are fitted to the ends of both the drag link and the steering tie rod.

Front springs are half elliptic and are flat under load. They have solid forged eyes on the master leaves. Shock absorbers of Rolls-Royce design are fitted at the front of the chassis. These are of the friction disk type, two leather conical shaped cuts fitting between conical steel disks. A spring, readily adjustable for pressure, forces the disks into contact. The rear springs are of the flat cantilever type, and as they have numerous leaves the friction between leaves is sufficient for damping the spring action, hence no shock absorbers are used at the rear.

The front axle is an alloy steel forging, and the steering knuckles are of the inverted Elliott type, with the pivot axes inclined so as to meet the ground at the center point of tire contact. The steering arms are fixed to the knuckles in a very secure manner. A flange is forged on the steering arm, which abutts a similar flange on the top of the steering knuckle, and the two flanges are bolted



Gasoline tank

together. Steering arm forgings are finished by filing all over and are then examined microscopically for flaws. This method of finishing up parts is used throughout.

The generator, which is of the Lucas make, is driven from the front of the gear box by a leather link V belt. The belt tension can be adjusted by means of a nut located on the outside of the frame. Voltage control is by the third brush system. A pressure of 12 volts is employed and the wiring is on the insulated return principle, except, of course, as regards the ignition wiring. The switch box, located on the instrument board, contains the battery cut-out switch, lamp switches, generator field fuses, charging switch, terminals for the generator, battery and lamp connections and a socket for an inspection lamp. A junction box is fitted to the front of the dash on the right-hand side. The cables leading from this junction box are inclosed in aluminum conduits or troughs bolted to the front side of the dash. These troughs are easily removed for inspection and give a neat appearance to the wiring.

The starter is located on the left-hand side of the gearbox and drives to the secondary shaft of the gearbox through a jaw clutch. A planetary gear on the starter, together with another on the gearbox, connected by a chain drive, give a total reduction from the starter armature to the crankshaft of 23 to 1. The sprocket wheel at the transmission is provided with a friction coupling to protect the starter and its gearing in the event of a backfire. A sectional view of the starter drive mechanism located on the transmission is shown in Fig. 3. The jaw clutch A is engaged automatically by an electro-magnet energized when the starter button is depressed. The operating motion is transmitted to the clutch through the rod B extending through the hollow secondary shaft of the gearbox. Referring to the drawing of the starter drive, power is received from the starter by the sprocket C, is transmitted through the friction coupling D to the central pinion E of the planetary set. The ring gear F of this set is held stationary and the power is taken by the planetary spider G, a part of which is forged integral with the hollow shaft H passing through the gear box secondary shaft. This planetary gear gives a reduction of 6 to 1.

All exhaust fittings are either riveted or acetylene-welded. The exhaust gases, before entering the muffler, are passed through an expansion chamber. Both the expansion chamber and the muffler are lagged with asbestos covered with a steel sheath to prevent heating of the body. An exhaust cut-out is provided.

The gasoline tank, of 21 gal. capacity, is made from tinned sheet steel. All joints are lapped, soldered and riveted. There are several baffle plates which stiffen the the tank. All tanks are tested under hydraulic pressure. As the gasoline enters the tank it is filtered through a monel metal screen of very large area, and on leaving the tank it passes through another monel metal screen. The tank is suspended by hangers from the frame passing over the ends of a tube extending centrally through the tank lengthwise, and is held from rotating by a stay from the rear cross member of the frame to the filler fitting.

The frame side members have a section 6 in. deep and are strengthened by an under-running truss. They are made of nickel steel. All cross members are of tubular form, made from seamless nickel steel tubing and are secured to the side members by drop forged fittings pinned and brazed. No rivets are used in the frame, all parts being secured to it by taper bolts passing through taper reamed holes.

A NEW parallel attachment for drawing boards, which does away with the use of the T square, has been placed on the market by the New York Blue Print Paper Co. It is claimed to be more convenient than the T square and also to give better results. The metal parts of the Precise parallel attachment are of aluminum and the whole attachment weighs under 2 oz. These parts comprise one plate with double pulley, one plate with two small pulleys at the ends of the straight edge, four brackets with a hole in each, a small grip to hold the cord firmly and sufficient silk cord for operating. The double pulley acts as a T square head, being provided with a shoulder for the purpose. The cords, running parallel, are hidden in the straight edge. The straight edge can be quickly adjusted to any angle desired and can, it is claimed, then be depended on for parallel line work.

Seasonable Announcement of Spring Top

AN automobile top which rises automatically as soon as a button is pulled to release a spring is manufactured by the Automotop Corporation. The bow sockets of the top are of the same form and bear the same relation to each other as in the ordinary top. Springs located between the body and the upholstery impart to the bow sockets the necessary motive power. Concealed hangers located inside the car are invisible from the outside of the car at all times. A pull button, situated at any convenient part of the car, releases the bow sockets from their hangers. This pull button is connected to the hanger finger releases by coppered steel wires. When thus released the spring actuated fingers throw themselves clear of the bows, permitting the springs to raise the entire top out of its boot into the final position of the main bows. From this point of operation the linkages connecting all of the bows come into play through the weight of the bows and top fabric, causing the entire top to assume its final horizontal position. It is then only necessary to pull down the snap locks fastening the forward bow to the windshield posts. A fabric side curtain pocket extending across the forward bow when the top is up covers the nest of bows, fabric and hangers when the top is down.

To take down the top, the windshield fasteners are released and by a light pressure of the hand on the forward bow, the entire top is pushed back into the boot and the hanger fingers snapped over the bow sockets. The top can be put up almost instantly, and taking it down requires less than fifteen seconds.

Refinements in a Battery Ignition System

Novel features claimed include a straight line contact with one floating point which prevents pitting. Duplex system differs from other systems in that either high frequency spark or single spark can be used as desired.

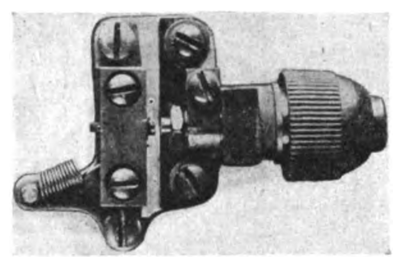
By J. Edward Schipper

THE Philbrin battery ignition system, which has been on the market for a number of years, has been refined in several details and brought up-to-date. The system was exhibited at both the New York and Chicago shows and is being offered for all lines of automotive work.

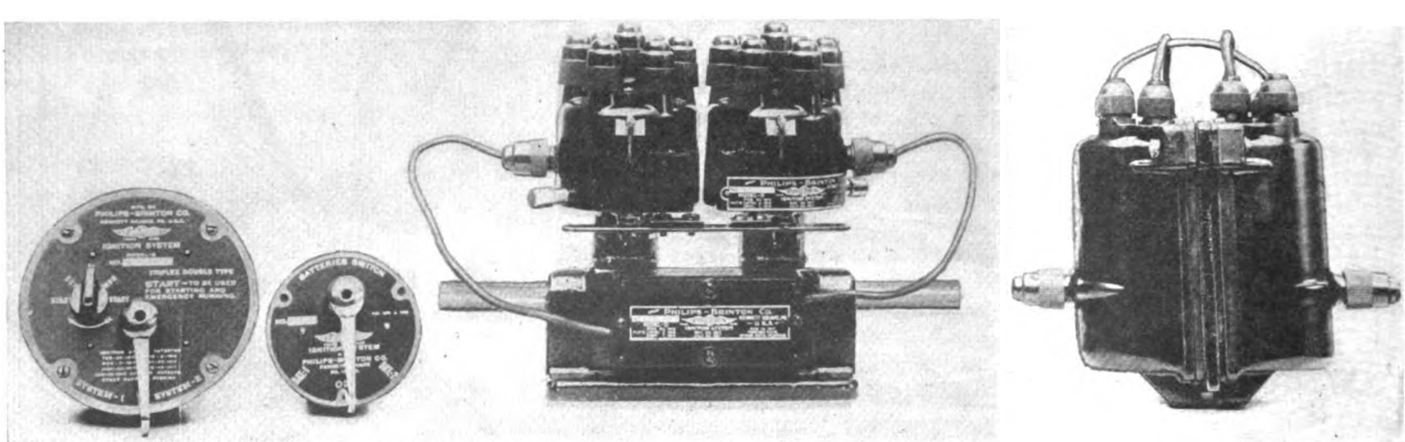
It is an open circuit system incorporating some features which are claimed to be unique. These include a straight line instead of a swinging contact movement of the interrupter movable part, said to insure uniform contact over the entire surface, and a floating contact shaft in the adjusting screw. This is free to move back and forth or revolve and is held in position by a helical spring. This spring imparts a turning movement to the contact shaft, which prevents pitting and mating of the points. A third feature claimed as an advantage is that the circuit is closed gradually and at the point of maximum saturation is broken instantly by the contact plunger dropping abruptly off the end of the cam tooth.

Probably the feature of greatest interest is the condenser, which is made up of sheets of aluminum foil with one layer of hard and one layer of soft paper in between. The condenser is wound in cylindrical form over a quarter inch mandrel. This is slipped into a seamless steel tube. The tube with this filler is then put into a steel die, placed in a punch press and pressed into the rectangular form. By this means, it is claimed, a substantial decrease in the distance between conductors is obtained by bringing the layers of paper and foil into intimate contact with each other. The leads, 3/32 in. wide and .003 in. thick, extend across the full width of the conducting plate, and are secured in place with shellac. Over each lead is placed a protecting covering of varnished paper, which is also held in place with shellac. It is an objection to the use of aluminum foil for condensers that it is difficult to make a satisfactory connection to the leads, but it is claimed that by the method above described a perfect connection is obtained between the brass and aluminum, as the raw edges of the brass strip are forced into the aluminum while transforming the shape of the condenser in the die.

The process of impregnating the condenser is as follows: The leads are connected in a 220-volt circuit in series with a lamp which is before the operator. The condenser is then placed in a bath of wax, the temperature of which is approximately 280 deg. Fahr. In the course of 10 sec., bubbles are seen coming from the ends of the condenser. Owing to the high temperature of the wax, moisture between the folds of the condenser and in the paper is converted into steam. This steam acts as a conductor of the current. In about 15 sec. the lamp (which is in series with the condenser) is seen to glow faintly. Meanwhile, the bubbling at either end of the condenser has become quite violent, as the steam, escaping from the condenser, tends to cause a partial vacuum, thereby drawing in the wax which takes the place of the moisture that has been expelled. The light glows brightly up to the point of maximum conductivity of the steam saturated condenser. After that point the light gradually dims as the dielectic strength of the condenser



The Philbrin single-spark interrupter



Parts of Philbrin ignition systems

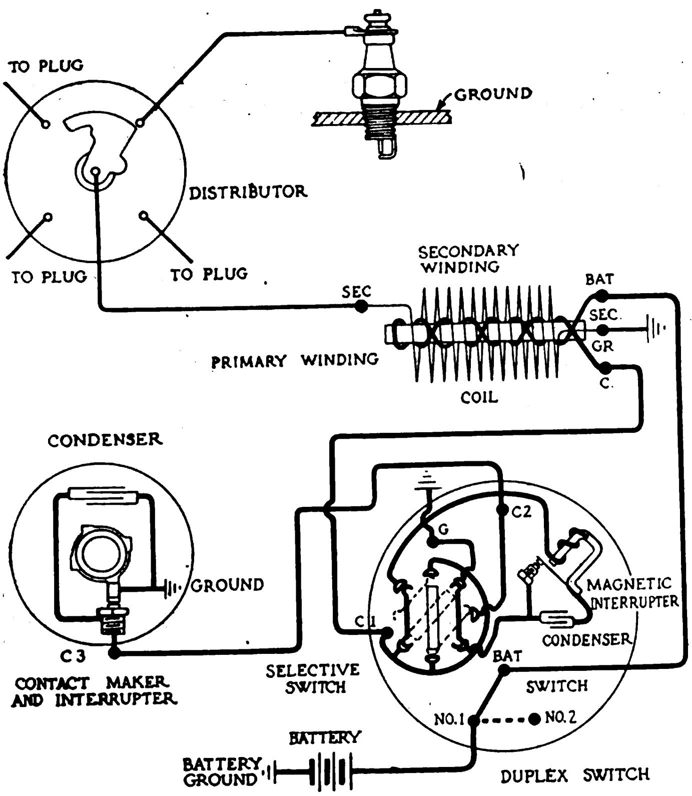


Diagram showing principle of operation and internal winding of Philbrin duplex ignition system

builds up due to the absorption of the impregnating wax until the light goes out entirely. The condenser is then left in this bath about 25 min. so as to insure thorough impregnation, the current being kept on throughout the whole period. Previously, it was necessary to dry the paper carefully before using, but in this process the moisture in the paper is utilized to help impregnate the condenser.

The coil is of the non-vibrating, open core type. The primary winding consists of two layers of wire wound around an iron wire core. This primary is secured in a laminated tube having 1/16 in. thickness of wall and composed of layers of "Kraft" paper and varnished paper.

The secondary, which is made in two sections, is mounted on the outside of this tube. Two and one-quarter turns of varnished paper are used for the insulation between the layers of the secondary winding. The coil is embedded in a bakelite case, which makes it oil and moisture proof.

The Philbrin duplex system differs from other ignition systems in that it uses either the single spark or the high frequency spark. These combined systems employ the same coil and distributor and are controlled by a common switch. In this switch is located a magnetic interrupter or high speed vibrator. This vibrator produces from 50,000 to 60,000 sparks per min. For some classes of work a frequency in excess of 100,000 is used. This switch is provided with a selective switch button which selects the system desired, either the single spark or the high frequency.

When the single spark system is being used, the timing is done by breaking the primary circuit. When the button is in the high frequency position, the magnetic interrupter in the switch is operating continuously. The timing and distributing is done by means of a distributor blade with a trailing tail, and the action is as follows: When the forward edge of the blade is approximately .015 in. from the distributor pin, the spark jumps to that point and the sparks are distributed to that cylinder throughout the power stroke. As the tail of the blade leaves this pin the sparks continue to jump back to the pin, since the cylinder connected is under a lower compression than that connected to the pin which the forward edge of the blade is there approaching, until the forward edge of the blade is within approximately .015 in. of this distributor pin, when ionization of the air takes place and the spark jumps to this distributor pin and repeats the same cycle of operations.

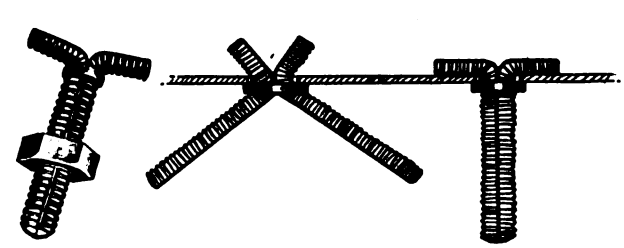
These sparks are synchronized, as no commutator is employed in the primary circuit, but the circuit is closed through the magnetic interrupter as long as the switch is in this position. Each time the high frequency system is turned on, the polarity is automatically reversed, as the button is turnable only in a clockwise direction. This system is used for starting a cold motor and for emergency running, as when excessive oil conditions are encountered, or when a poor carbureter adjustment is used. It is not possible to have both the single spark and the high frequency turned on at the same time.

The single spark double system is used where it is desired to produce two synchronized sparks in the cylinder of an engine. Two distributors and two contact makers are then employed, only one of the contact makers being used at a time, the other being held in reserve. With this system, no high frequency spark is employed.

The duplex double system is used where it is desired to produce two synchronized sparks in the cylinder of an engine. This is done by employing one contact maker and two distributors mounted on a common base. Two coils are employed with their primaries wired in series. This produces two independent secondary sparks, each going to its own distributor. The high frequency system operates the same as before described.

The triplex double system is used where it is desired to produce two synchronized sparks in the cylinder of an engine. The only difference between this system and the duplex double system is that two contact makers are provided, but only one is used at a time, the other being held in reserve. This system was developed at the request of the Baldwin Locomotive Works three and one-half years ago. It is claimed that it made the use of large locomotives practical and that other methods had utterly failed on these locomotives.

A SPLIT bolt which can be secured into the panels of sheet metal bodies is manufactured by the Savage Expansion Bolt Corp. It may be described as a length of screw-threaded rod split lengthwise through the center, each half having one end turned at right angles. To fasten the bolt into a sheet metal panel which is accessible from the outside only, a round hole the size of the bolt is made in the panel, the halves of the bolt are then put with their turned head portions together and the bolt is forced through the hole, after which the nut is drawn up tight, anchoring the bolt firmly in the panel. If it is desired to secure a sheet metal or similar bracket to the panel, this can, of course, be put under the nut.



A split bolt for use in sheet metal body panels

Hardness and Its Relation to Ductility and Fatigue Range

The meaning of the term hardness is clearly explained, and various methods of measuring this quality are discussed. The relation of hardness to ductility and fatigue range is pointed out and the tendency to demand high ductility at the expense of other desirable qualities is discussed.

By Dr. Walter Rosenhain, F.R.S.

THERE are probably few properties of metals which are of more general importance to the engineer than "hardness." This is a property, or more probably a group of properties, which it is extremely difficult to define and which it is correspondingly difficult to measure, but the term none the less corresponds very definitely to something which, in engineering materials, and particularly in such structures and machines as are involved in automobile engineering, is extremely necessary. It is, therefore, worth while to devote a little consideration to what we really mean by the term "hardness" and how we can define and measure it in the first place and how it is to be best obtained and utilized afterwards.

The general conception of "hardness" is perhaps best understood if we think of it as the opposite to "softness." Now softness is the typical quality of a material which is easily displaced. If we can push a finger into a piece of clay or wax, we speak of it as "soft." Hardness, therefore, as the opposite of "softness" we may fairly regard as the power of resisting displacement or "pushing away." But here we meet the real difficulty—that materials can be "pushed away" in a variety of different ways. The pushing away may be done by direct pressure or thrust, as when an indentation or punch-mark is made, or it may be done by lateral pushing or shear, as occurs in some forms of cutting or scratching, or—finally—it may be done a little piece at a time, by abrasion or wear. Yet we term the power of resisting all these different kinds of displacement "hardness" and try to measure this property by measuring the resistance of the metal to one or other of these various forms of displacement.

That "hardness" measured in one of these ways does not necessarily measure the power of resisting the others becomes quite plain if we think of one or two special cases. Thus suppose that a material or body were built up out of a regular pile of small, strong flat plates placed one upon the other. Indentation of such a pile by vertical pressure upon its upper surface would meet with very great resistance, and the apparent "hardness" would be very great. Yet the little flat plates could be pushed away along the surface with great ease, and hardness measured as resistance to that kind of displacement would appear very low indeed. Again, whole layers of the little plates could be pushed along with comparative ease if a lateral or shearing force were applied, and again the "hardness" would be low. Although this is an extreme case, and real metals are not built up in such a peculiar manner, yet it serves to illustrate the point that we cannot, as a matter of course, assume that a body having a high hardness number as measured by indentation methods, must also have high resistance to scratching or abrasion. In actual materials there is, fortunately, some linking up of properties. As a rule, for instance, high tensile or compressive resistance is accompanied by high resistance to shear also, and this generally implies a high degree of resistance to local shearing or abrasion.

There are, however, important exceptions to this latter rule. All ordinary tests are made fairly rapidly and can therefore ascertain only the properties of the material as it exists at the moment of test. Yet there are some materials which undergo very profound changes of internal constitution and structure if exposed to certain special working conditions. This applies, for example, to a certain group of special alloy steels which contain enough of the added elements, such as nickel or manganese, to keep them in what is known as the "Austenitic" condition, in which they are relatively soft and non-magnetic. Some of these steels, if subjected to mechanical deformation involving plastic strain, become converted into what is known as the "martensitic" state, in which they are very "hard" and magnetic. Tested in the ordinary way, such a steel appears to be comparatively "soft." Yet the wearing surface of a rail made of such a steel becomes converted, under the stresses to which it is locally exposed, into the hardened form of the steel and resists wear to a most surprising extent. From the point of view of hardness-testing, materials which behave in such a manner are fortunately rare, but for many purposes they are extremely and increasingly important.

The usual methods of hardness-testing rely upon the assumption that resistance to one method of displacement implies a corresponding degree of resistance to all other methods of displacement. Since in many materials there is an approach to compliance with this assumption this is a useful process, but it is important to bear in mind that it is based on such an assumption which may, and sometimes does, break down seriously here and there.

The most widely used of all hardness tests, particularly in England, is the Brinell ball indentation tests. This test is so well known that it is not necessary to take up space by any detailed account of it, and we need only consider it from a very general point of view. What it measures is something which depends upon the general "strength" of the metal; in most cases the "Brinell Number" is directly proportional to tensile strength. This, no doubt, is an advantage where it is desired to save the trouble of making a tensile test if a simpler test like the ball-test will serve the purpose, but from the point of view of actual hardness-testing it is less satisfactory, since it becomes clear that the ball-test shows little or nothing that is not already known from the well-explored tensile test. None the less, the real utility of the ball-test cannot be

doubted, particularly since it allows of the rapid exploration of relatively large surfaces of metal with a view to ascertaining the uniformity of the material. The test can be applied without seriously damaging many objects, and for the purpose of ascertaining whether a given material has been correctly made or treated so as to attain a given degree of "hardness," it leaves little to be desired except in the case of extremely hard metals, such as fully hardened steel. There, the deformation of the ball becomes serious as compared with that of the material under test and the resulting figures are apt to have very little value. Apart from that difficulty, however, uniformity of ball-hardness is a very good guarantee, throughout successive productions of the same kind, of uniformity of composition and treatment. On the other hand, comparison of the "hardness" of widely different materials in terms of the ball-test is a much less reliable proceeding.

The Brinell or ball-indentation test has the further rather serious disadvantage that the "hardness number," which is generally found by dividing the load applied by the total area of the spherical indentation produced, is not entirely independent of either the size of the ball or the load employed. It does not, therefore, represent as it is intended to do, the load per unit area which the metal under test is capable of supporting without further deformation. Attempts have been made in two directions to improve upon the ball-test by making the indentations in a slightly different way. In one, usually known as the Ludwik Cone Test, the indentation is made by pressing into the metal under test a steel cone having a sharp point. All indentations made with such a cone are geometrically similar and there is no need to use different cones with metals of widely different "hardness"; the applied load can be varied without destroying the geometrical similarity of the indentations. This method gives excellent results until the attempt is made to apply it to very hard materials—then the point of the cone, and with it the test, are liable to break down, as the local stresses become excessive.

In another direction the attempt has been made to replace the hardened steel ball of the Brinell test by a flat-ended parallel punch. This method also presents important advantages, but it has not yet been studied sufficiently to be capable of general application. In an entirely different direction, however, important modifications of the hardness test have been developed. These developments have taken the direction of making the application of the indenting instrument very brief indeed and thus of producing an indentation by impact rather than by "static" or steady pressure. In England this line has been followed by Prof. Edwards, who was mainly concerned with a problem which is of very direct importance in connection with automobile engineering. This is the determination of the properties of materials at such high temperatures as those to which they are exposed in the interior of an internal combustion engine. Pistons, valves, cylinder heads and even connecting rods all have to do their work at temperatures which are high enough to produce a material change in all the physical properties of our materials. It is, indeed, often found that of two materials the one which is weaker at the ordinary temperature is appreciably the better of the two at, say, 600° Fahr. (250° C). Tests of hardness at various temperatures are, therefore, of very considerable interest and value. There is, however, a difficulty in making such tests in the ordinary way by the ball-indentation method, because the exposure of a hardened steel ball to such a temperature as 600° Fahr. for any length of time softens and spoils it to a serious extent—and at still higher temperatures, such as come into consideration in connection with exhaust valves, the steel ball becomes useless if left in contact with the heated test-piece for more than the fraction of a second. It is for this purpose that Edwards has developed a ball-impact test, in which the heated test-piece is indented by means of a cold steel ball which strikes the test-piece and rebounds from it before the ball has had time to be affected.

As a general rule, Edwards has found that the ball-hardness as found by impact does not vary very much from the "static" hardness in such cases where direct comparison can be made, although a few metals furnish marked exceptions to this parallelism. Curiously enough, iron or very mild steel is one of the most striking exceptions. This case has, however, been fully explained in a manner first anticipated by the writer and subsequently fully verified in his and other laboratories. It is found that the exact manner in which iron, or the "ferrite" of very mild steel, undergoes deformation is different when the stress applied is "static" from that which occurs when the stress is due to a blow or is "impulsive." In the latter case, microscopic examination shows in the vicinity of the indentation a large number of fine lines running across the ferrite crystals—generally known as "Neumann's Lines," which are entirely absent near a statically-produced indentation. This discovery, while it explains the discrepancies in impact hardness numbers, is still more important because it shows definitely that what occurs in ferrite under impact is quite different from what occurs under steady loading—a circumstance which lends added importance to the whole question of impact testing.

The method of ball-hardness testing under impact, as developed by Edwards, still relies—both for tests at ordinary and at high temperatures—upon the subsequent measurement of the indentation produced. A somewhat similar impact-hardness test has been developed—at an earlier date—by Shore in quite a different direction. In the well-known Shore Scleroscope, which originated in America, the impact of the "hammer" also produces an indentation but no measurement of this is included in the test—all that is measured is the height of rebound of the hammer after falling upon the surface to be tested from one standard height. What the height of this rebound really measures is simply the amount of energy left in the hammer after making the indentation. This depends upon how much the metal which has been struck has been displaced or indented and how much energy has been absorbed in this process of indentation. There are also other losses of energy, such as the heat generated at impact and losses by elastic and other displacements of the piece of metal as a whole, but in most cases these are fortunately small enough to be neglected in this type of test. To a certain degree of approximation, therefore, the rebound in the Shore Scleroscope measures the resistance of the metal to indentation under impact, and this is clearly, a particular kind of "hardness." Again, in the majority of materials, this property appears to run nearly, if not quite parallel with ordinary Brinell ball-hardness, and—like the latter—with tensile strength. There can, therefore, be no doubt as to the convenience and value of the Scleroscope test, provided that it is used with care and with an intelligent appreciation of its limitations. In order to realize how serious these limitations may be if the test is applied—for example—to a thin piece of metal not quite adequately supported, it is instructive to make a Scleroscope "hardness" determination on a piece of fairly stout celluloid sheet, first placing this direct on the metal base of the Scleroscope and afterwards interposing a fairly thick piece of india-rubber. In the latter circumstances the rebound is higher than that obtained from the hardest steel. On the other hand, it is only fair to point out that for the testing of very hard materials, the Scleroscope working with a diamond-ended "hammer" has a distinct advantage over other ball-indentation methods. It appears to the writer, however, that while the Scleroscope in its present

form is very simple and easy to use, its value as a testing instrument would be very much increased if it were possible to vary the height of fall of the hammer.

Quite recently, Dr. Haigh, at the Royal Naval College, Greenwich (England), has worked out an entirely different method of hardness testing. Recognizing the difficulty which arises in the case of hard metals from the deformation of the ball or other tool used for making indentations, Haigh has developed a method in which the indenting implement and the indented specimen are made of the same metal and are caused to indent each other in a symmetrical manner. Two square-sectioned bars or prisms of the metal to be tested are prepared of exactly equal dimensions; these are then held securely in jigs and, with their lengths at right-angles to each other, and edge crossing edge, are pressed together with a known load. The two prism-edges indent one another symmetrically, and the amount of this indentation is a measure of the hardness, just as in the Brinell test. This ingenious test is still in its infancy, and suffers from the obvious disadvantage that it can only be applied to specially prepared test-pieces, but it offers some entirely new possibilities in hardness-testing and it may be destined to throw new light on some of the difficult problems connected with this subject.

In addition to the purely mechanical tests of "hardness" which we have just considered, there are a number of others based on such methods as scratching or abrasion which do not appear to be as yet capable of any high degree of precision. So far as abrasion or resistance to wear is concerned, it still seems that actual trial in service is the only really reliable test where the comparison of different materials is concerned. At most, a test-model designed to imitate the conditions of service may be employed for trial purposes, but if the test is to be a quick one, the similarity to service conditions must inevitably be violated and the resulting data to that extent rendered doubtful. It is, therefore, reasonable to state the position in this way, that while ordinary "hardness" tests of the indentation or Scleroscope type furnish a general guide as to the "hardness" of metals even from the point of view of resistance to abrasion, it is not safe to rely too much upon such guidance except in the case of a single class of material in which the correlation between these tests and wear in service has been definitely established. To put the matter in concrete form, the relative degrees of hardening of a set of pieces of the same carbon steel could be safely ascertained by the ball or scleroscope test; but of a bronze and a steel giving identical "hardness numbers," one might give very much longer life in service than the other.

Ductibility

Even the general kind of guidance which can thus be obtained from ordinary hardness tests, however, is of immense value in the selection of materials and in deciding upon their treatment. That hardness is of vital importance in engineering construction is, of course, obvious. On the other hand, increased hardness nearly always brings with it a corresponding decrease in ductibility, and the rival claims of these two properties deserve a little consideration. Both the designer, the maker and the user of engineering products have a deep-rooted desire for ductility in their materials. It has, of course, been pointed out that an automobile back-axle which has been seriously bent by an accident is no more serviceable than one which has broken short off, and it is doubtful whether an accident is likely to be rendered less serious by the mere fact that damaged parts have given way by bending rather than breaking. The extreme demand for ductility which still exists in many quarters is probably to a large extent a heritage from the days—now seemingly remote, but really not very far back in history—when wrought iron was the principal material for all engineering construction. In that material, ductility stood for good quality in all respects and material which "broke off short" was rightly regarded with suspicion. When steel was first substituted for wrought iron, it was natural that the same demands for ductility should be made upon it, and in very mild steel these demands can of course be met. But the demand has extended, to a certain extent, to all other materials, and for many years engineers have thought it essential to sacrifice much to this requirement of ductility.

That there is need for ductility in many places is not, of course, to be denied. The exigencies of constructional operations often require a little "cold setting" of parts, and even where such operations are entirely avoided, the inevitable errors, or rather variations of workmanship still require that the material shall have the power to yield slightly in order to secure a more uniform distribution of load. But for these purposes, as a rule, quite a small degree of ductility is adequate; no adjustments of the kind mentioned demand any such ductility as would correspond, for example, to an elongation of 20 per cent on 2 inches in a tensile test. It would seem, therefore, that the real need for ductility for its own sake under service conditions is quite small. It is, therefore, only as a test for quality of the material that it can be given any very great importance. If that is the case, however, it should be regarded from a point of view rather different from that ordinarily adopted: ductility should only be valued as a quality to be aimed at so long as other and more immediately important qualities are not sacrificed.

Fatigue Range

Thus, in the majority of the working parts of an engine, it is the fatigue range—i. e., the range of alternating stress to which a piece can be safely subjected for an indefinitely long series of repetitions—which really measures the value of a material. Now this "safe range" under fatigue is associated very closely with the property of "hardness" which we are here considering, and like hardness, it can be obtained, as a rule, only at the expense of ductility. Now consider the case of a crank-shaft. Failure under fatigue is of vital importance; but provided the shaft will stand the small amount of straightening which may be necessary at one stage of its manufacture, of **what further use is ductility in a part which would become useless if it were a few hundredths of an inch out of line? Yet the demand for a relatively high degree of ductility in most specifications definitely limits the hardness and with it the safe fatigue range of the material employed.** Among materials having the same fatigue range, it would no doubt be justifiable to select that which showed at the same time the highest degree of ductility, although even there the selection should be based rather upon the results of a notched-bar impact test than upon ductility alone. But, **given a certain minimum amount of ductility, depending upon the nature of the service required, it appears to be traditional rather than logical to value higher ductility at the expense of hardness and fatigue resistance.**

More directly concerned with the subject of hardness is the question of material exposed to actual abrasive wear, such as gear-wheels, shafts running in bearings, etc. Here there are two divergent lines of practice which are of interest in the present connection. They may be described as the "case hardening" and the "all hard" respectively. So far as actual hardness tests are concerned, identical values can be obtained from materials of both kinds, although it is important to remember that in the ball-indentation test there is danger of obtaining much too low a value if the indentation is made in a very thin, hard case lying upon a soft core. With identical hardness numbers one may, in

this case where the materials are otherwise similar in constitution and structure, assume that actual wearing properties as against abrasion will be identical for the "cased" and the "all hard" materials so long as the case is not worn through. Actually, however, it is usually easier to obtain a high hardness number from a cased article than from one which is entirely hard. The reason is that a more severe quenching process can be safely applied to a properly cased article than to one which consists entirely of high-carbon steel. In the latter case the volume changes due to hardening occur throughout a much larger mass and there is a greater tendency to crack. In the cased article, on the other hand, flaking of the case may occur if the transition which occurs between case and core is not sufficiently gradual.

The sort of consideration just mentioned, which governs the degree of hardness attainable, applies also in other directions. Apart from the question of cost, the preference for cased articles to some extent derives its inspiration from the desire for ductility which has been discussed above. While the extreme ductility of a very mild-steel core encased in hardened high-carbon material can hardly ever come into play, there is yet something to be said on the other side. Where "all hard" steel is employed, the article is often so treated as to become fully hardened throughout, and the whole material is thus put into a condition in which there is a total absence of all ductility. This, it would seem, is carrying the doctrine of "hardness at all costs" decidedly too far, since some little degree of ductility is undoubtedly not only useful but even necessary in most engineering objects.

Looking back over the whole subject which we have here passed under review, it is clear that hardness and the other physical properties which appear to be so closely associated with it, are of fundamental value in engineering construction the further study of the methods by which it can be obtained and tested and measured is therefore a field of great importance.

Government Report of British Aircraft Autumn Trials

THE Air Ministry's report of last year's early autumn trials of British airplanes and land and waterplanes, including both normal and special commercial aircraft types, has recently been issued. The report eulogizes the progress made, especially in commercial type aircraft by way of contrast with those which were adapted for commerce from war machines. A special tribute is paid to British magnetos as fitted to the competing machines. The report says, "When a few mechanical details have been improved," there is little doubt that the British magneto will be the best in the world, and that the British manufacturers of magnetos as shown by this trial will "be ahead of any foreign rivals." The advantages of a fair margin of extra engine power despite the extra cost also are emphasized.

The report, like the trial, while useful technically, does not seem likely to help a revival of civil aircraft building which at the present is almost dead. The Government's decision to grant $300,000 this year as a conditional subsidy to aircraft builders, promulgated this week, seems to be timed auspiciously for this report, but it is felt that the sum is insufficient for any technical development. As matters stand only the Handley Page Co. seems likely to benefit, since it is the only one qualified to compete for the subsidy. The conditions prescribe that competing companies must be British, and must be able to show that on a maximum of forty-five days in each period of three months flights have been completed in both directions by aircraft of British manufacture, fitted with British made engines, within a fixed maximum period of time allowed for each journey.

The routes at present approved are London to Paris, London to Brussels, and London to Amsterdam. Extensions to these routes and additional routes, such as England to Scandinavia, on which the possibilities of a service employing flying boats or amphibian machines, or a mixed service of sea and land aircraft, can be demonstrated, may be approved.

The sum offered compares poorly with the amount, $750,000, recommended to be allotted by the Government's Advisory Committee in June last. Moreover, the scope is limited to continental routes. The aircraft industry naturally wants to develop inland air services, in which respect Great Britain compares unfavorably with France and Germany.

The following points are gleaned from a *Times* interview with Mr. Handley Page following the announcement of the Government's grant.

The sum, he considers, is good, having regard to the present financial stringency. It will be useful in developing long distance flights in other countries, such services being of the sort already subsidized by foreign governments. It may lead to reduced charges, since even the present scale of charges is profitable without obtaining full loads. There will follow development all round.

Mr. Handley Page, also, does not ignore the possible danger of a Government subsidy retarding progress because of the tendency to lean on Government support. But he seems more concerned that the help was not forthcoming earlier, as it might have prevented the passing out of certain pioneer aircraft firms. He also thinks that as the grant (at present) is for one year only, it is not likely to develop the betterment of the commercial airplane, because such new machines if put in hand now would not be ready for flying on service next year.

Lowering Costs by Greater Production

AN effort to obtain lower costs by greater production and increased efficiency instead of by lower wage scales is the general program of S. F. Bowser & Co., Inc., manufacturers of oil and gasoline storage systems, Fort Wayne, Ind., and is also the program of other local industries, according to S. B. Bechtel, manager of the Bowser plant. Labor during the year 1920, according to Mr. Bechtel, was unproductive generally and was only about 45 to 55 per cent efficient. Already this year, he declares, there has been an increase locally of 25 per cent in labor's efficiency. Labor alone is not held responsible for this condition by Mr. Bechtel, but industrial management is also declared to have been inefficient to a great extent during the period of war-time high prices and abundance of orders. During 1920 approximately 15 per cent of all local labor was absent on every working day and this has now been reduced to 2 per cent.

An Elevating Dump Body

Is designed for use primarily for dumping from an elevated position but can be used in same way that ordinary dump body is employed. Is operated by hydraulic hoist and is provided with 18 ft. telescoping chute.

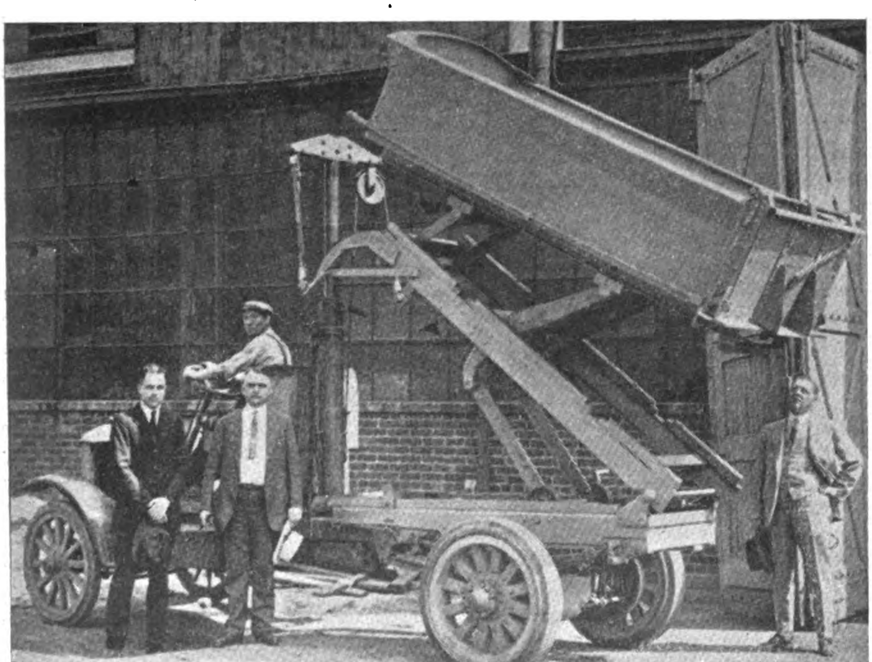
TO meet a demand for an elevating dump body embodying a simple operating mechanism, the engineers of the Federal Motor Truck Co. evolved the design herewith illustrated, on which a number of patents have been applied for. This body is intended to be used primarily for dumping a load from an elevated position, but it may also be used as an ordinary dump body.

This type of body is extensively used in the coal business, in road building (dumping into concrete mixers) and in garbage collection (dumping into a large body). It is composed of three principal units—a dump body, very much like an ordinary body; a hydraulic hoist, and an elevating mechanism under the body. The body has two dumping positions—the elevated position, which raises the lower end of the body 6 ft. above the ground, and the ordinary dumping position.

The dump body is the ordinary type of body with a flat, sliding bagging chute door in the tail gate and carrying an 18-ft. telescoping chute in a cradle under the body. The hoist is the Federal Motor Truck Co.'s standard heavy duty type, except that cross arm at top is secured in a solid instead of a pivoting bracket.

The elevating mechanism comprises a frame extension arranged above the chassis frame, strengthening the frame and carrying the shafts, brackets, etc.; an elevating frame pivoted at the rear and carrying the lifting arm at the front and the main elevating lever at the center, this frame being elevated just as with the ordinary dump body; a main elevating lever pivoted at the center of elevating frame, the lower end being anchored to the frame by pull rods and the upper end elevating the body; pull rods pivoted at the lower end of the main elevating lever, the lower ends having a cross shaft which is engaged or disengaged by release hooks; a shaft holding two large cast steel hooks is connected by brackets to the frame extension just above the rear axle. On the right end of this shaft, and outside of the frame is a hand lever, which throws the hooks forward to engage the pull rod shaft for the elevating position, or backward to release the pull rods for the ordinary dumping position. The front elevating member, being joined to the body and the main elevating frame, lies almost flat when the body is down, and advances toward an upright position to give sufficient angle for dumping when the body is elevated.

Body in ordinary dumping position



Body elevated into high dumping position

The body is elevated into the dumping

Proposed Methods of Automotive Gear Inspection

Gear Makers Association developing standard practice for inspection of their product. Size of hole, wear of gages, tapered holes, keyways, tooth bearing, splined shafts and methods of test are some of items considered.

A SUB-COMMITTEE of the American Gear Makers Association Standards Committee, of which E. J. Frost is chairman, is developing standard methods for inspecting gears commercially. At the Lake Mohonk meeting of the A. G. M. A. an interesting report was presented on the subject of inspection, but no action was taken on it. The following rules for gear inspection, therefore, are at present only committee recommendations, but it is quite likely that at the next meeting, to be held at Cincinnati in the spring, they will be made recommended practice by the Association.

Inspection of Bores—Cylindrical holes up to 3 in. diameter shall be inspected with "will and will not go" plug gages, the "will go" end to have a diameter the same as the smaller limit and the "will not go" equal to the larger limit given on the customer's drawing.

Tolerance for wear to be allowed before discarding gages:

TABLE I

Size of Hole, In.	Class 1	Class 2	Class 3
0 to ½	.00007"	.0001"	.00015"
½ to 1	.00010"	.00015"	.00020"
1 to 2	.00015"	.00020"	.00030"
2 to 3	.00020"	.00025"	.00040"

Tapered Holes

Tapered holes shall be inspected with tapered plug gages and the quality of fit determined by painting the gage with red lead or prussian blue, when a full bearing shall be shown.

Proper depth of reaming or grinding shall be indicated by a stepped shoulder located at either end of the plug, as the case may require, the height of the step and relationship to the taper agreeing with limits given on customer's drawing.

Keyways

Keyways in both straight and tapered holes and for both single and multiple keys shall be inspected for width of keyway by using "will and will not go" bar gages, gaging the width only.

For alignment and depth, a plug gage shall be used, which has body diameter equal to the small limit of the hole and a key long enough to reach the entire length of the keyway, the width and height of the key gage agreeing with the customer's small limit.

If the maximum depth is important, a similar gage shall be used as a "will not go," having a key height equal to the maximum shown on the customer's drawing.

Woodruff Keys

A hardened gage similar in shape to a Woodruff key but slightly thinner than standard, shall be used, and a keyseated ring gage slid over it. The latter should check for depth and alignment and also show if radial. If both minimum and maximum depth are required to be verified, two keyseats can be put in the ring, these agreeing with the two limits on customer's drawing.

For width, use a "will" and "will not go" bar gage, both ends of which shall agree with the customer's limits.

Test Stands

The smaller sizes of spur, spiral and internal gears, shall be checked for pitch diameter, eccentricity and irregular teeth by inspecting on a hand stand, the essentials of which should be, rigidity in construction so that none of the parts can spring, and one rigid and one freely sliding head, so arranged that the movement of the sliding head will actuate a dial indicator.

The studs on which the work is mounted shall be at right angles with the surface on which the one head slides and parallel with each other within 0.002 in. in 12 in.

The size of the studs shall not be smaller than the "will go" end of the plug gage used for gaging the hole, and the same tolerance for wear shall be allowed as given in the table.

This stand may also be used for determining the quality of tooth bearing, provided satisfactory master gears are used.

For the determination of noise, a power stand shall be used, the essentials of which shall be the same as those of the hand stand, except that it shall be provided with power which may be applied in either direction, and there shall be a power brake.

The indicator shall be omitted and the movable head shall be controlled by a screw adjustment and clamping device.

In the hand test stands, it will be found an advantage, when once the stud holes are accurately bored in the heads, to bush them with hardened steel bushings, straight on the outside and tapered on the inside, so that the wear of putting the studs in and out can be largely taken care of by the taper, and new bushings can be substituted when the old ones are badly worn, without disturbing the accuracy of the original bored holes.

Master gears in pitches finer than six, shall be within an eccentricity limit of .001 in.

In disputes concerning eccentricity, where master gears of proven accuracy are not available, a hardened gear with teeth cut away so as to have but one of its teeth in engagement at a time, may be used by rolling through the arc of contact and then ratcheting to the next tooth.

Bevel gears shall be inspected on hand or power stands for quality of bearing, and on reversible power

stands equipped with hand brake, for noise.

These stands shall be rigid in construction, the belt pull shall be downward rather than upward, so as to tend to seat the movable heads rather than pull them away from their bearings, the spindles shall lie in the same plane and be at right angles with each other within an error of .002 in. in 12 in., and the tapers of the holes in the spindles shall, if possible, agree with those in the bevel generating machines, so that work can be examined without removing from the arbor on which it was cut.

In straight tooth bevels, conical pointers may be used to prove whether the teeth are radial or not.

The above applies to such gears as are used in truck, tractor and automobile construction and not to the larger mill gearing.

Tooth Bearing

Questions of tooth bearing shall not be determined in the final assembly, but by inspection on test stands, as noted above.

Splined Shafts

For width of spline, root and outside diameter, use a "will" and "will not go" snap gage, made to dimensions given on customer's drawing for the work, or use a micrometer set to the same dimensions.

For accuracy of spacing, use a ring gage having one portion ground to maximum diameter of outside of keys and at one end an annular portion with a diameter of hole equaling the maximum diameter of the body of the shaft and milled and ground away so as to leave projections whose width and angle of face shall equal the minimum space between keys as given on the customer's drawing.

Sizes of Collets for Holding Stem Gears

Use holes in collets or bushings equal to the maximum shaft size plus the amounts given in Table I, when new, and also allow the same amount as given in Table I for wear before discarding.

Fixtures for Testing Internal Ring Gears When Held by the Outside

Add to bore of fixture, when new, the amount given in Table I and also a like amount for wear before discarding.

Shifter Grooves

For diameter of bottom of groove, use "will and will not go" snap gage, slightly thinner than width of groove, or use micrometers.

The gage should be made to limits given on customer's drawing.

If the shifter groove has a fillet in the corner, a similar allowance plus clearance shall be made in the gage.

For width of groove use a "will and will not go" bar gage made to customer's limits for the work.

Thread Gages

Use plug or ring gages made by a reputable concern and in case of dispute, have checked by the Bureau of Standards. "Will and will not go" gages should be used for accurate work.

Machine for Checking Tooth Shapes

It is recommended that this association have designed and built an instrument for determining the accuracy of involute curves in cutters or work, and that it be installed in the Bureau of Standards at Washington.

Disputes

All disputes over the accuracy of micrometers, gages, etc., may at the request of buyer or seller, be referred to the Bureau of Standards, whose report shall be accepted as final and the expense of such testing borne by the owner of the instruments tested, unless otherwise agreed upon.

In making comparisons of dimensions, the same temperatures shall be used as are maintained by the Bureau of Standards.

First American Airway to Be Constructed in 1921

THE establishment of well organized air routes throughout the country is essential to the progressive development of commercial and civil aviation. With properly equipped airways, flying will become a safe and efficient mode of traveling in this country. For this reason the proposed creation of a model airway between Washington, D. C. and Dayton, Ohio, during 1921 is a fact of special interest.

The project is being fostered by the Army Air Service, which is able to provide such equipment as is available for creating the route, but cannot purchase land or make financial expenditures. The expense will fall upon local civic and commercial organizations to whom the benefit of the airway will eventually accrue.

Certain stations on the airway will have gasoline, oil and spare parts for both Government and civilian aircraft. Charts will be made of the entire route at the request of the Army Air Service and also a photographic map of the route will be prepared. Oblique aerial photographs of every city, landmark and landing field will be taken and arranged into such form as to provide a guide to the route. Copies of these books can be signed for at one end of the route and turned in at the end of the journey. Flyers along the route will be in constant radio communication with each other and with the various ground stations and in case of fog or clouds will be directed along the route by radio. Should a group of commercial ships desire to negotiate the route unequipped for wireless, then an airplane so equipped can be dispatched with them along the route and they can "follow the leader" in perfect safety.

A system has been devised for marking the landing fields along the route for purposes of identification and will serve as an aid to navigation. Each State is being divided into one hundred parts from west to east, and lettered alphabetically north to south, each letter representing a distance of 30 miles. A field in the northern part of Eastern United States marked O-55-B would be in Ohio, about half way across the State, and between 30-60 miles below the northern border. Since commercial aircraft will probably negotiate a 30-mile distance in slightly over 15 minutes locations by this system are sufficiently close together for navigating purposes. More minute detail will be provided in certain subdivisions of the system at or near landing fields and in the laying out of signs and letters.

A Machine for Multiple Drilling and Tapping

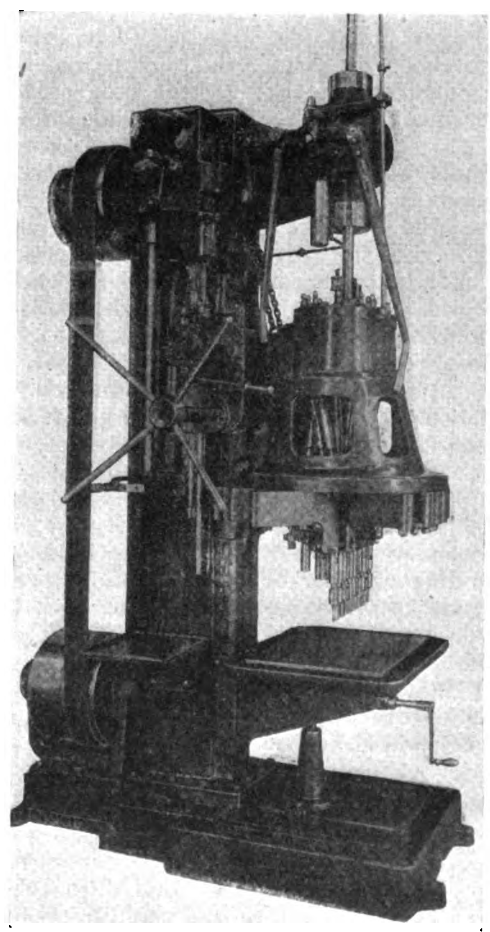
Employs automobile type friction clutch in main driving pulley to enable the power to be shut off when a change in direction of rotation of spindles is made, thus overcoming disadvantage of earlier machines.

GREAT success has been attained in the multiple drilling of motor castings and other similar parts, the reduction in cost over the use of a single spindle drill being such that no progressive concern can afford to do without multiple drills. Multiple tapping of holes has also been attempted, but has not been uniformly successful, owing to the want of a satisfactory device for reversing the direction of spindle rotation when the taps have reached a predetermined depth. Friction clutches that have been employed for this work operated at too low speeds, and would not retain their adjustment. Positive clutches employed were subject to too great shock, and consequently were short-lived and subjected the machines to too severe strains. The Fox Machine Co. has placed on the market a multiple spindle tapping machine which is claimed to overcome these objections.

The upper drive pulley at the rear of the speed change box is built into a single drive plate friction clutch. Any of the standard automobile clutches, such as the Hoosier, Borg & Beck, etc., can be used on this drive. At the front of the machine is a lever with a cam surface, which either disengages this friction clutch or allows it to engage, thus furnishing the means for stopping and starting the machine.

On the vertical drive shaft to the head is a positive driving clutch with twelve right hand teeth on one side and twelve left hand teeth on the other. These teeth engage opposing members, which are carried by bevel gears, the gears being driven by a bevel pinion mounted on the horizontal shaft which runs into the speed change box. The operation of this clutch, which is used for reversing, is also controlled by a lever at the front of the machine. This lever is interconnected with the lever which disengages the friction clutch.

When the tapping lever is moved from forward to reverse position, or vice versa, the first part of the movement disengages the friction clutch driving the machine. Further motion of the lever carries the solid tooth driving clutch from one position to the opposite one, this being accomplished while the power is off. After the positive clutches are in engagement, the final motion of the tapping lever allows the friction clutch to again engage, and the power is then transmitted through the positive clutches, driving the spindles in the reverse direction. Special provision is made against the possibility of the teeth of the clutches striking one on top of the other when being reversed, which would prevent the clutches from becoming engaged.



Multiple spindle machine for drilling and tapping

When the tapping attachment lever is pulled forward, the spindles are given a right hand rotation. A heavy spring is put under compression, and is latched in this position. An adjustable stop on the vertical stop rod is so set that when the taps reach the desired position, the stop comes in contact with the trip arm, which releases the spring held under compression. The movement of this spring carries the tapping attachment lever automatically from the forward to the reverse position. Thus, the operator does not have to trip the tapping mechanism when the desired depth of hole is reached.

The machine illustrated taps 5/8 in. holes in cast iron plates, 1¼ in. thick, in 5 sec., a maximum of 6 hp. being consumed. The main drive shafts are mounted upon ball bearings.

Special attention is called to the fact that all springs used are exceptionally heavy and entirely inclosed, so that the operator cannot tamper with them. Another feature is that, after the tapping attachment lever is thrown forward and the automatic trip locked in position, the operator can move the tapping lever back and forth, to reverse the direction of the taps, as rapidly as he desires, before the taps reach their bottom position. This is of special importance in the case of breaking a tap. The operator reversing the spindles under these conditions does not affect the tripping of the mechanism when the taps finally reach their lowest position. The multiple spindle tapping machine shown is a Fox D-22. This mechanism is also applied to the D-12 and D-32 machines.

THE Packard Motor Car Co. has designed a 12-cylinder V-type aircraft engine developing 400 hp. for altitude flying, known as Model 1237. The weight is 735 lb., giving a specific weight of 1.85 lb. per hp. It is built on the over-dimensioned, super-compression principle.

Where Is the Motorcycle Going?

With the coming of business depression and the falling off of foreign orders, the old question is again arising as to "What's wrong with the motorcycle?" This article is the first of a series of two which discusses from the standpoint of an interested observer the conclusions reached after a careful survey and a general analysis of the situation

By Norman G. Shidle

CONSTRUCTIVE criticism is almost an essential to the healthy growth of an industry. Probably no industry has been subjected to more criticism of this—and other kinds—than the automobile industry; certainly no industry has grown more rapidly and gained so strong a position in a comparatively short time. Certain phases of such criticism can sometimes be given better by an interested and intelligent onlooker than by those actively interested in the advancement of a particular part of the industry.

An examination of the field would indicate that such criticism has been lacking to a large extent in the motorcycle industry. Outside criticism has usually come from those whose only knowledge consists in having the quiet of their neighborhood disturbed by the open-cutout speed demon who still leaves behind him an oral as well as a visual impression in the being of bystanders. Criticism from this class of persons has been widespread and vigorous, but is not usually constructive. Much of it can never be printed in the Sunday school books.

The fact that the motorcycle industry is so largely concentrated in a few organizations has made the motorcycle press very strongly dependent upon the good-will of these few for its existence. As a consequence, criticism from this source has sometimes been weighed not alone on its qualities of justice in deciding whether or not it should be printed, but also in regard to the likelihood of its meeting with disfavor in one or another of the controlling concerns. Such a condition is not always conducive to the publication of that frank and honest criticism which is one of the chief functions of the business press and which ultimately works to the progress and advancement of the industry as a whole.

Progress of the Industry

It is worth while to examine what has been the progress of the motorcycle industry under these conditions, how it stands at the present time and along what lines future development is likely to go. The discussion logically divides itself for analysis into these sections:

1. Is the motorcycle industry progressing at a normal rate; that is, does it show a normal healthy growth during recent years?
2. Merchandising:
   a. Past policies.
   b. Present ideals; how far realized; co-operative possibilities.
   c. Future development.
   d. Undeveloped merchandising fields.
3. Motorcycle design:
   a. Mechanical features.
   b. What weight machine for future business?
   c. Weight and cost of machine as related to future development of the industry.

The progress of an industry can be measured in a general way by production figures, sales—as denoted by registration and export figures—and by financial statements. The latter standard is difficult to use for the motorcycle industry because of the numerous firms that have entered and left the field during the last ten years. Production figures, however, can be estimated with a fair degree of accuracy, while export and registration figures are available in most instances.

The chart shown herewith presents the relation between motorcycle production, domestic sales and exports since 1913.

An examination of the production curve alone shows that the progress of the industry has not been steadily upward. Beginning at a peak in 1913, motorcycle production dropped sharply until 1915, when an upward turn was taken. This rise continued rather gradually until 1917, when another drop began. Since 1918, however, production has increased each year, the most rapid rise taking place during the last year.

Nor is there any indication that this variation in production progress is due to the coming and going of the several companies which have entered the field for a short time and gone out. Something like this same line would be found if production were charted for only the companies which have remained steadily in production throughout this period.

In other words, the curve indicates that during the last eight years the motorcycle industry has been doing little more than holding its own. While it is true that during 1918 and 1919 the manufacturers were unable to supply the domestic demand for machines, it must be remembered that these years were in every sense of the word unusual merchandising years; years in which the demand was abnormal and automatic; years during which heavy demand for machines did not necessarily indicate any real progress for the industry.

When it is recognized that there are some 14,000,000 more people in this country to-day than in 1913, it becomes evident that the motorcycle industry has not progressed in proportion to its increased possibilities for development, even taking into consideration the unfilled domestic demand of 1918 and 1919.

But any consideration of motorcycle progress, especially during recent years, must take into serious account the export trade. The accompanying chart shows, for instance, that over half of the 1920 production was shipped to foreign countries. This fact alone might account to a large extent for the extremely slight increase in domestic motorcycle registrations during the last year.

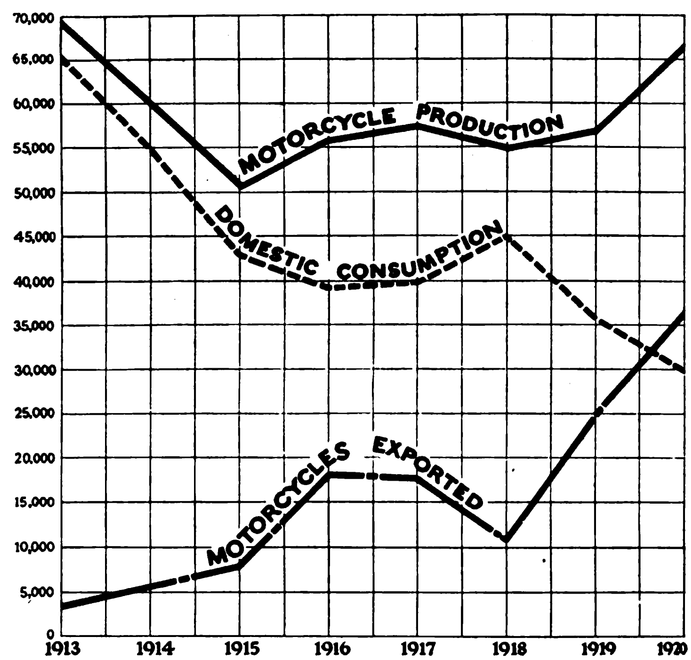
It is interesting to trace the gradual increase in the percentage of foreign business done by the motorcycle industry. The percentage of production sent to foreign countries since 1913 is as follows:

	Per cent		Per cent
1913	5.8	1917	29.2
1914	10.4	1918	18.6
1915	15.7	1919	44.0
1916	30.8	1920	55.5

These figures show a steadily increasing proportion of American motorcycle production being sold abroad. This increase is materially broken only by the 1918 figure, which can probably be accounted for by the fact that some of the motorcycle plant manufacturing facilities were turned to other lines of government war work as were many automobile plants; also to the difficulties of making foreign shipments during this period.

Studying these percentages in connection with the chart and the curve showing the relative trend of domestic and foreign business, certain rather definite indications stand out.

While motorcycle production during these years has been about holding its own, domestic business has fallen off very greatly. This indicates that only because of greatly increased foreign business has a market been found for the same number of machines as were formerly produced. Even recognition of the unfilled domestic demands of 1918 and 1919 cannot nearly account for a difference in domestic consumption between 1913 and 1920 of 31,000 machines.



Relative trend of motorcycle production, domestic consumption and exports

This means that there has been during the last eight years a drop in domestic consumption equal to the production capacity of the largest manufacturer and more than equal to the actual annual production of any of the large manufacturers for at least seven years. In other words, the industry as a whole at the present time is dependent upon the maintenance of this large foreign business if it is even to continue the production of as many machines as in the past. And the trend of the domestic consumption curve is downward at present, although domestic business, in the long run, must probably be relied upon as the foundation of the prosperity of the American motorcycle industry.

This not a healthy condition. What has brought it about?

When the failure of motorcycle registrations to increase was brought to the attention of one manufacturing executive recently, he said something like this: "Foreign orders have been very enticing during recent years. We have had large orders for twenty-five, thirty or fifty machines in many cases from one source. These orders came almost unsolicited, and, being for large quantities, gave us an opportunity to plan our production regularly for a period ahead. We took these orders for this reason. Consequently, we could not supply the domestic demand for a time and have not intensively cultivated the domestic field during recent years."

To an outside observer, this might seem a somewhat short-sighted policy. It savors a good deal of taking the path of least resistance without due consideration of the more fundamental and enduring phases of the motorcycle merchandising problem. The very fact that many of the foreign orders came without any great effort on the part of American manufacturers is some indication that the demand was abnormal. In any business the mere filling of present orders is not conducive to permanent progressive development.

The result in the domestic field is likely to be dissatisfied dealers, for one thing, and a natural clogging up of domestic merchandising channels due to disuse. Foreign business is highly desirable and the foreign field should undoubtedly be cultivated and extensively utilized. But when it overshadows domestic trade so that there is a possibility of decay setting in, a danger is presented.

This does not necessarily mean that such a danger point has been reached in the case of the motorcycle industry, but the trend of the curves is such as to make a serious consideration of this factor very pertinent. The figures and curves presented would seem to indicate the justice, in a general way, of this conclusion.

The motorcycle industry in the United States has, at the best, merely held its own during recent years. One present need is a careful study of the domestic market, and an intensive effort at development and cultivation in this direction. This development to be molded along lines directed toward a permanent progress for the industry, on the basis of far-sighted intelligent merchandising policies, with an increasing emphasis upon the permanent features and a decreasing consideration of purely temporary advantages.

Domestic Merchandising

There have been innumerable defects in the domestic merchandising of motorcycles. Some of these major defects still appear. No one recognizes this fact more fully than the executives of the various motorcycle companies, and definite efforts to remedy the faults are being put under way. The chief difficulties are so well known and understood as to need little discussion, so far as looking backward is concerned. They may be listed here, however, as a foundation upon which to base a discussion of remedies and future possibilities. The chief troubles are probably included in this list:

1—A class of dealers, skilled perhaps on the mechanical phases of their business, but lacking in merchandising ability and the social graces which accompany it.
2—Lack of cleanliness and attractiveness in dealers' showrooms and repair shops.
3—The predominating class of riders being those who pay little attention to personal cleanliness; and who

pay a similar amount of attention to the feelings of others by operating their machines in a noisy, unpleasant manner.

4—The overemphasis of the sporting phases of the motorcycle, particularly as shown in the speed and power mania.

5—The failure of some manufacturers and many dealers to visualize the merchandising possibilities of the motorcycle in a broad way; to build their business with an eye to permanent future progress.

6—The numerous road records that have been attempted, with the effect of advertising the motorcycle favorably to a few and unfavorably to many. In the same class were the motordrome races of several years ago.

A previous paragraph has stated that these troubles have been recognized by the manufacturers. This statement, perhaps, should be qualified to some extent, since the manufacturers do not entirely agree that all of the points mentioned are defects, and there is not entire accord as to the way in which even those recognized as defects should be remedied.

In the matter of raising the level of dealer representatives, progress is undoubtedly being made by the chief manufacturers. A survey of the dealer organization of one of the largest reveals a considerable number of high grade business men, intelligent, well-dressed, pleasant, courteous, and efficient. But it can scarcely be said that this number is anything like a majority as yet. Progress is being made; but is it being made rapidly enough? If it is necessary to wait until all the low grade dealers die before replacing them with progressive high grade men, the motorcycle business may suffer serious difficulties in the meantime.

Obviously, it would be absurd to disrupt a dealer organization by making a wholesale clean-out at any given time, but it must be recognized that every dealer with a dirty shop, interested primarily in mechanics to the detriment of courtesy, is a definite drag on the industry as a whole. The type of dealer determines to a large extent the type of rider. And every noisy, dirty, hell-bent-for-election rider loses more potential motorcycle sales than the fact of having him for an actual buyer is worth.

The very fact that the motorcycle industry is concentrated in a few hands sets up the danger of its getting in a rut. No industry can stand still for an indefinite length of time. It must go forward or it must go backward. There is always the danger in any small group of becoming bound by tradition, of becoming tied up in the round of "the way it has always been done," of lacking the shock of contact with new ideas that is necessary to progress.

Tradition when it is thoroughly good is an invaluable aid to any industry. But when it contains a number of unfavorable features it is a very great handicap. Thus in the matter of motorcycle dealer representatives, it would seem that a very definite and straightforward campaign were necessary to raise the level of this group if the industry is to go forward to its best possibilities.

This campaign can take two lines:

1. The education of the present dealer personnel.
2. The changing of the present personnel for a higher grade of men.

At the present time most of the effort is being extended in the first direction. It is a slow process, since very bad material upon which to work is presented in many cases. The manufacturer having obtained the vision of future progress for himself must sell the ideals and methods to many individual dealers, some of whom, possibly, are utterly incapable of understanding them.

While the work of dealer education is undoubtedly helpful and necessary, it is questionable whether or not it can get results quickly enough to offset in any marked degree the harm that this "uneducated" class of dealers is constantly doing to the ultimate progress of the industry.

With these facts in mind, the possibility of very definitely starting out to wipe the slate clean insofar as this type of dealer is concerned, is worth very serious consideration by motorcycle manufacturers.

The matter of cleanly and attractive salesrooms would be automatically solved by the substitution of a higher grade of dealers. The problem of rider education would also be somewhat softened. This would be true not only because of the fact that the dealers would naturally appeal to a better class of rider, as well as to those who now ride, but also because the dealer himself would set an excellent example as a rider.

The truth of these facts is attested by an observation of the results obtained already by that group of dealers already in the business who may be said to constitute men of superior ability and merchandising effectiveness. There are such men selling motorcycles to-day. But there are not enough of them. And the favorable impression which this small group makes upon the public at large is still much more than offset by the unfavorable impression made by the other group, which still predominates rather strongly.

Weight of Chassis Components

IN his paper prepared for the annual meeting of the S. A. E., D. McCall White gave some figures on the weight of parts of the LaFayette chassis which are of interest. It should be pointed out that this chassis has a 348 cu. in. engine developing 90-95 hp. at 2800 r.p.m.

The weight of a stripped chassis, complete with electrical equipment, battery, radiator casing, oil, grease and four tires, is 2570 lb. The weight of the engine averages 7.2 lb. per hp. complete with flywheel, all accessories, including carbureter, throttle and ignition, control rods, lighting and ignition units ready to run as in the car. The transmission complete with clutch and torque ball casing, universal joint and brake equalizer, weighs 160 lb. The front axle weighs 106¾ lb. The rear axle complete with torque rod, propeller shaft and driving shafts, weighs 385.94 lb. The steering gear complete with control rods, steering arm and ball, tubes, spark and throttle gears, weighs 34¾ lb. The weight of other parts is as follows:

	Lb.	Oz.
Clutch hub	4	12
Piston	1	9¼
Single connecting rod (finished*)	1	13¼
Forked connecting rod (finished*)	1	15¾
Camshaft (rough)	22	
Camshaft (finished)	9	12½
Crankshaft (finished)	31	
Wrist pin (finished)		2¾
Tappet roller pin (finished)		.64
Tappet (finished)		2.6
Valve (inlet and exhaust same wt.)		4.8
Tappet set screw (finished)		½
Fan and generator shaft	1	4½
Main transmission shaft	5	10¾
Rear hub (finished)	6¾	
Propeller shaft	18½	
Rear driving pinion and shaft	4	6.4

*Without bushing.

Program Outline for the Foreign Trade Convention

Topics selected for annual gathering in Cleveland in May are of constructive value. Advertising and financing are prominent among the subjects. Motorcycle foreign trade has been developed in excess of domestic trade. Automotive developments in many countries.

THE program for the Eighth National Foreign Trade Convention, which will be held in Cleveland May 4, 5, 6, 7, has been outlined and is quite constructive in its scope. The general theme is "American Foreign Trade and Its Present Problems." The program, following the reception and preliminary meetings on Tuesday, is as follows:

WEDNESDAY, MAY 4

First General Session .... 10:00 A. M.
1. American Trade and Its Influence on Foreign Exchange.
2. The Causes of Inflation and Its Effect on the Exchanges.

Second General Session .... 2:30 P. M.
1. Influence of American Investment Abroad.
2. The Settlement of Our Export Balance.
3. Frozen Credits—What They Are and How to Thaw Them.

Group Sessions .... 8:00 P. M.
Group I—Commercial Education for Foreign Trade.
Group II—Foreign Credits (in Co-operation with the National Association of Credit Men).
Group III—Problems of the Export Manager (in Co-operation with the Export Managers' Club).

THURSDAY, MAY 5

Third General Session .... 10:00 A. M.
1. The Effect of Double Taxation on Foreign Trade.
2. Foreign News and Foreign Trade.
3. Discriminations Against American Trade.
4. A Reasonable American Policy for Foreign Loans.
5. Adequate Foreign Service Essential to Our Foreign Trade.

Group Sessions .... 2:30 P. M.
Group IV—Special Export Problems of the Manufacturer (in Co-operation with the American Manufacturers' Export Association).
Group V—Foreign Trade Advertising.
Group VI—Inter-American Trade Relations.
Group VII—The Interest of Agriculture in Foreign Trade (in Co-operation with the American Farm Bureau Federation).

FRIDAY, MAY 6

Fourth General Session .... 10:00 A. M.
1. American Maritime Policy.
2. Marine Insurance.
3. Inland Transportation for Foreign Trade.
4. Return Cargoes.

Group Sessions .... 2:30 P. M.
Group VIII—Banking Service to Foreign Trade (in Co-operation with the American Bankers Association).
Group IX—Merchandising and Forwarding (in Co-operation with the American Exporters and Importers Association).
Group X—Trade Relations with the Far East.

Banquet .... 7:30 P. M.

SATURDAY, MAY 7

Fifth General Session .... 10:00 A. M.
1. Reports of Group Sessions.
2. Final Declaration of the Convention.

—

Tientsin as a Car Market

APPROXIMATELY 600 motor cars are in daily operation in Tientsin, China, which is rapidly becoming an important motor car market, as dealers there handle the cars and trucks going to Peking and a wide stretch of Chinese territory, including Mongolia and stretching over into many parts of Manchuria and Siberia. According to the Oriental Motor of Shanghai, the city of Tientsin has six car importers, which handle a number of American and European lines.

Several passenger services are operated out of Tientsin and one is contemplated between Tientsin and Peking. The latter trip, it is calculated, will require somewhat more than five hours of traveling.

Efforts are being made by the North China Motor Club to revise the motor license system, which is now quite bad. Each of the foreign concessions, of which there are six, and the native city require a separate license and, unless each license is paid, driving is restricted.

Recently Consul General Fuller of Tientsin wrote to the Department of Foreign and Domestic Commerce:

"There is considerable complaint, however, because there are no distributers of American automobile accessories, especially tires, in China. Any American firm which maintained ample stocks of accessories at a central distributing point, such as Shanghai, and could supply local houses without delay would increase the sales of its product in the district."

—

British Tractor Prospects

THE position and prospects of farm tractor business in Britain may be gaged from the following comments based on information disclosed recently in the legislature:

According to a Ministry of Agriculture return, the acreage of land in England and Wales under arable cultivation on June 4 (last) was 12,020,000 acres, being 289,000 acres less than a year earlier, and 379,000 acres less than on June 4, 1918. On the other hand there were 1,022,000 more acres in arable condition on June 4 last than on the corresponding date in 1914.

Allowing 250 acres per tractor, the added 1,022,000 acres arable since 1914 would find work for 4088 machines and for 1516 more, but for the return of 379,000 acres to fallow since 1918. On the same basis of computation, the 12,020,000 present arable acreage should require 48,080 tractors

to work it steadily, without allowing for a contingent—say 10 per cent—of stand-by machines.

It is doubtful if there are more than 12,000 tractors available in Britain, but since the holding of the tractor trials last year, and the possibility of its becoming a yearly event farmers are awakening to their value and necessity.

The high cost of farm labor, foodstuffs for cattle, and the better financial return more or less guaranteed to farmers for their cereals, are factors tending to the good of the tractor movement in Britain. Nevertheless it is necessary that the price be got down to not exceeding $1,300 (pre-war rate of exchange) if their sale is to be developed.

The type looked for is something on the Fordson model, but not necessarily with a barrel-like cast chassis. The mechanism must be enclosed and self oiling and the drawbar capacity should be equal to three ploughs cutting 5 x 10 in. (British farmers won't plough deeper or wider than 6 x 11 in. in light land, and two furrows on heavy land). The haulage capacity should be equal to pulling a 4 ft. x 8 in. threshing machine, and the belt power should cover the requirements of that size—the largest and most used—of threshers. The belt should lead fore and aft and not transversely and should be capable of some variation of speed.

Makers here are beginning to provide two diameters of pulley, usually one at either end of shaft, and others are listing a pair of interchangeable pulleys of varying diameters. The high speed engine tractor won't suit. The sort required is a medium speed engine of fairly large bore and preferably with vertical cylinders, amply jacketed to prevent boiling. Detachable wheel grips—preferably angles—also are essential, and they should be such as can be removed or replaced in an hour.

Foreign Trade is Major

IT is interesting and exceptional to learn that there is one branch of the automotive industry that has regarded foreign trade so highly that it has accorded to this trade a greater distribution of its products than it has to the domestic trade. This is the motorcycle division of our industry. On another page of this issue a motorcycle manufacturer is quoted as quite frankly stating that his company found foreign trade so easy to handle and so satisfactory, that no attempt was made to meet all of the domestic demand. As a result of this peculiar situation, the foreign trade in motorcycles has become greater than the domestic trade.

This incident should be a worth while thought to some other automotive exporters. It is also true that one large producer of trucks has built a considerable trade by looking to only foreign outlets.

Czecho-Slovak Show

THE week of May 28 has been selected for the thirteenth International Automobile Show to be held in Czecho-Slovakia, according to a report of the Bureau of Foreign and Domestic Commerce. It will be under the direction of the Czecho-Slovak Automobile Club (Ceskoslovensky Klub automobilistu) in the Industrial Palace and other buildings at Prague and cars, trucks, tractors, motor plows, motorcycles and equipment will be exhibited. Seventy-four exhibitors were represented at the successful showing last year. Application blanks and information may be obtained from the club or from the Czecho-Slovak Legation at Washington.

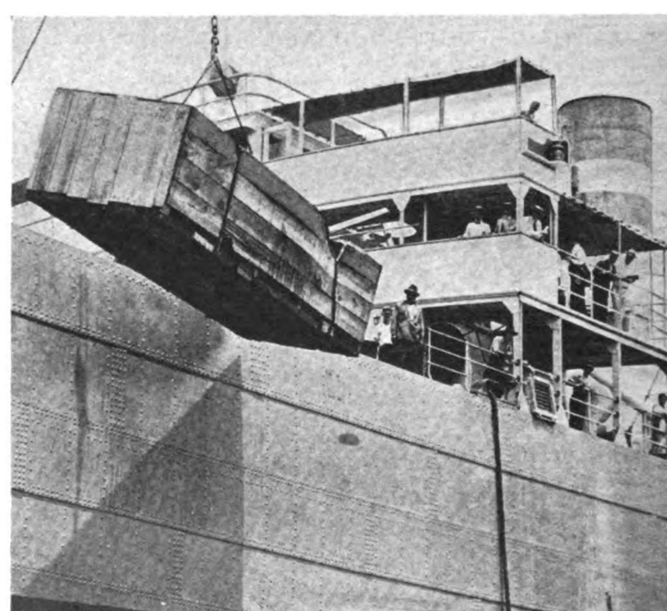
An Australian Car

A MELBOURNE correspondent of the London *Times* "noting the inability or unwillingness of British motor car makers to cater for the Australian trade," (to quote his own words), points out that Australia has need of a light, medium-priced and economical car; that America has filled the bill, but the advanced rate of exchange and customs duty has tended to raise the price unduly. Accordingly an effort to market a home-made car is being made at Sydney. There a "Six," made of American parts, is being assembled and, he says, is sold as an Australian car! It is proposed now to make all of it excepting the engine in Australia, and the engine is to be of Australian design. The scheme is largely due to S. Hamilton Grapes, who for several years was the Australian representative of the Albion Motor Co. of Glasgow. The selling price of the new "six" is estimated at below $2000.

Market for Spark Plugs

THE markets for spark plugs in China, India, Indo-China, Japan, Netherlands, East India and Australia are discussed in a report of the Bureau of Foreign and Domestic Commerce dated Feb. 4, 1921. In making up the report, several of the consular officials have given late estimates of the number of automobiles in their districts. The consular district of which Tientsin, China, is the center, reports a census of from 1500 to 2000 passenger cars, 60 motor trucks and 75 motorcycles. Ceylon is said to have about 3000 motor cars and 1600 motorcycles. Indo-China is estimated to have from 5000 to 6000 motor vehicles, and the statement is made that in Japan there are considerably more than 6000 automobiles and 3000 motorcycles. The number of cars in the Melbourne, Australia, consular district (including the states of Victoria and Tasmania) is placed at 22,265, with motorcycles approximately 13,685.

An Export Crating Experience



Here is a graphic lesson in export packing. You will note, by looking closely at this photograph, that the truck crate has broken under the strain of the lifting chains. This photograph was made on the New Orleans dock by a photographer who was seeking to illustrate an article on export shipping. It was not made as a warning to shippers, but that appears to be its best use. The lumber specifications of this crate are not available, but the shipping firm has had much experience in export

Wide Field for Motor Trucks in Textile Industry

A survey conducted by *Textile World* indicates that many textile manufacturers are getting great satisfaction from the use of trucks. Light trucks are finding increasing favor, while many users are studying the pneumatic equipment problem seriously. The results of this valuable survey are summarized here.

JUST before the business slump hit the textile trade an interesting survey was conducted by *Textile World* concerning the use of motor trucks in that industry. A questionnaire was sent out and replies were received from 414 mills located in various parts of the country. In selecting the list of mills to whom the questionnaire was sent due regard was paid to size, character of product and location, with idea of showing average conditions in the various branches of the industry and different sections of the country.

The foreword to the report of this survey states that "as much care was taken to exclude large mills known to be extensive users of motor trucks, as in eliminating a large number of small mills that could not be expected to use trucks. In fact, with the exception of one large corporation using 55 trucks, none of the other mills reporting uses more than seven trucks. It would have been quite possible to load the report by adding a half-dozen large corporations who are known to have anywhere from 25 to 35 trucks, and we are not certain that such inclusion would not have given a fairer average result, for one of the surprises of the questionnaire has been the large number of small mills reporting the use of two or three trucks ranging up to five tons each."

The answers to certain of the questions bring to light interesting information of vital interest to those concerned with merchandising trucks. The report as published by *Textile World* comprises not only a presentation of figures obtained but an exceptionally clear analysis of what those figures mean in the light of the circumstances involved. For this reason the report is summarized here as being of special value to truck sales managers.

The questionnaire included ten questions, some of which brought forth more accurate answers than others. Several of the questions pertained to the cost of operation of the trucks. The statement of the report concerning the answers to this group is rather striking:

Answers to these questions, the report states, "are too incomplete to render them of material value, and disclose the fact that very few textile manufacturers keep cost and other statistical data relating to their trucking." It is likely that a similar survey in other fields would show similar results, and the lack of accurate operating cost data in connection with most trucks is a factor which must always be taken into consideration.

Despite the fact that accurate costs had not been kept, however, the answers to the question "Relative cost of present haulage as compared with old?" indicates, according to the report, that "the great majority of textile manufacturers using motor trucks are entirely satisfied with the results obtained, even in certain cases where they estimate that the cost of motor trucking is greater than that of haulage by horse-drawn vehicles." Seventy mills answered this question intelligently and of this number 42 stated that motor trucking is less expensive than horses, while 13 said that the expense was about the same. The other 13 believed the cost of trucking to be greater.

Number of Firms Using Trucks

The 414 answers showed that approximately half of the firms used motor trucks. Of this number 153 actually owned trucks, while about 20 per cent more have their trucking done on contract. There was no indication that the location of the plant had any influence on the use of trucks, although bad roads might limit the use, of course, in a specific instance.

Small Trucks Popular

One important question related to the size of trucks used. The replies indicate that there is more work for light trucks of less than 1½-ton capacity than for any other kind. The proportion is as follows:

	Number	Per cent of total
1½ ton or less	118	35.4
2-3 ton	95	28.4
3-4 ton	66	19.8
5 ton	45	13.5
5-10 ton	10	2.9

These figures indicate that more than 60 per cent of the trucks used in this industry are 3 tons or less in size. This carries out the opinion expressed by some truck experts that the trend in truck use will be toward larger numbers of medium-sized trucks, with the gradual reduction in numbers of the larger capacity vehicles.

Touching upon this angle of the matter, the reports say: "When textile mills first started to utilize motor trucks they confined their purchases to two to five-ton sizes for their heavy trucking of raw materials, and finished goods; they were not long in learning that for small loads and quick work these heavy trucks were uneconomical and the use of trucks of 1½-ton and smaller has been rapidly increasing. The tendency to-day among textile mills of medium and large size is to utilize a standard equipment consisting of one or more trucks of 1½ tons or less, a two to three-ton truck for medium-sized loads and a three to five-ton truck for heavy work; another important development is the utilization of five to ten-ton trucks for the hauling of coal and ashes, and some of the smaller mills located at a distance from railroads are using these big units. Another interesting

development among textile mills is the utilization of both small and large motor buses for transporting operatives to and from their work, thus making it possible to secure the services of help in adjacent towns and villages. The equipment of the largest mill organization reporting is as follows: 1½ tons and smaller, 12; 2 to 3 tons, 18; 3 to 4 tons, 20; 5 tons, 5. It may be of interest to note that most of the finishers use medium and large size trucks, while knitters favor the small sizes. The finisher's loads are usually heavy and the haulage for long distances, while knitter's loads are usually light. The character of goods trucked by cotton and woolen mills varies as widely as the size, character and location of the mills themselves, but the tendency, as previously noted, among medium and large-sized mills is toward a standardized equipment consisting of small, medium and large-sized trucks. The same statement applies to the large silk mills, although the use of 1½ ton and smaller trucks is quite common in this part of the industry."

Opinions on Pneumatic Tires

Two of the questions asked related to the use of pneumatic tires. These questions were as follows:

1. Do you use solid tires?
2. What do you think of pneumatics on trucks?

Answers to these queries brought 140 replies. Of this number 117 or 84.5 per cent, are using solid tires, while the other 23, or 16.5 per cent, reported pneumatics in use.

The replies indicated, however, that textile users of trucks are giving very serious attention to this question. They show that the present use of pneumatics in the textile industry is confined chiefly to the lighter trucks and for long distance work where speed is an important factor.

A considerable number are also using pneumatics on the front wheels of heavy trucks with the idea of saving the engine from unnecessary vibration. There seemed to be considerable sentiment, however, for the use of pneumatics on heavy trucks for long distance work for the purpose of decreasing vibration and thus lengthening the life of the truck and also for making possible a higher rate of speed.

Trailers

Only 9 of the 145 mills which answered the question regarding the use of trailers stated that they did use such equipment. On this point the report states that "most of the mills answering in the affirmative make use of trailers for long distance haulage of raw material or finished goods, either between widely separated mills of their own, or to and from freight stations, processing plants, or raw material markets. It may also be stated as our opinion that demountable bodies are much more likely to become standard equipment among textile mills for trucking purposes than trailers."

Type of Goods Hauled

The truck salesman must know, of course, the type of goods to be hauled if an intelligent sale is to be made. The report asked the various manufacturers what sort of material they were carrying in their trucks and brought forth rather comprehensive answers on this point. A summary of the information contained in these answers is presented by the following quotation from the report:

"Textile raw materials, goods in process, finished goods and mill supplies are the principal classes of merchandise for which motor trucks are used, and they are handled in a large variety of forms, but very few of them require the use of special bodies. Textile raw materials are handled in bales and bags ranging in weight from 150 to 1000 lb. Yarns and other stocks in process are handled in bags and cases as a rule. Finished goods are usually cased or baled, and range in weight from 100 to 500 lb. Mill supplies are of large variety, but require no special form of truck or body that is not utilized for other similar purposes; for instance, many mills are using five to ten-ton coal trucks for their coal and ashes, while others are making use of special bodies for carrying lumber."

The answers to this questionnaire as a whole present a great deal of information specially valuable to the salesmanager and offer a number of suggestions for further investigation and analysis.

Structural Analysis and Design of Airplanes

FOR the official information and guidance of the Air Service and those interested in aeronautics, the Engineering Division, McCook Field, recently published a book bearing the above title. The more specific object of the book is to give designers reasonable methods for the structural analysis and design of the component parts of an airplane structure. The view is expressed that the acceptance and use of a single system of analysis will tend toward uniformity in design and ease in checking calculations and in making comparisons between different airplanes.

The general procedure followed in the book is to take as examples of the different structural units of an airplane, actual standard designs chosen to illustrate as many phases of the work as possible, and to follow through each step of the analysis and structural design. All the main equations and computations are given in full. These are supplemented by explanations, drawings and diagrams where necessary for clarifying the text.

The following chapter headings may give something of an idea of the scope and method of treatment of the work: Principles of Applied Mechanics and Strength of Materials, General Considerations, Wing Stress Analysis, Miscellaneous Designs, Airplane Chassis, Control Systems, Control, Surfaces, Fuselage, Appendix.

The fact that the book was compiled by the Structure and Aerodynamics Branch, Airplane Section, Engineering Division, is sufficient guarantee of its authoritativeness.

Vital Factor in Time Study

THE essential relation of the time-study man to harmonious industrial relationships has been emphasized in AUTOMOTIVE INDUSTRIES from time to time. The opinion of a well-known consulting engineer on this point is of interest. William O. Lichtner of the Thompson Lichtner Co., said recently before the Society of Industrial Engineers:

"One of the first things to be impressed upon the minds of our would-be time-study man is that he is studying human beings like himself. This means that no one should be allowed to enter this field until he has learned the lesson of properly regarding the human element."

Automotive Fuel Injection Engines Possible

Editor AUTOMOTIVE INDUSTRIES:

It is hardly necessary to assure you that work such as that accomplished by Mr. Ricardo and described in his article in your issue of Feb. 24 ought to make most of us feel very small indeed. A point to emphasize, however, is that, for experimentation on such a variety of engines and with such a variety of experimental features, great resources appear to be necessary. As far as this country is concerned, I think even now, after so much awakening to the importance of the subject of fuel economy, it is not yet superfluous to emphasize to manufacturers the fact that investigation and research pay, and that for real progress quantitative measurement and scientific detail analysis are every bit as necessary as invention.

AUTOMOTIVE INDUSTRIES deserves high credit for bringing this paper of the great English engineer before the American public. There is no question that in this country we have now talent enough and inventive genius enough to duplicate and perhaps improve upon any results obtained abroad the minute we are set going strong in the right direction. If Mr. Ricardo's paper is to serve as a stimulus for work in a new direction, it is somewhat unfortunate that it should have come when capital is so reluctant to go into research and new development work.

In one point I should like to differ with Mr. Ricardo. He speaks of his bitter experiences with Diesel engines. Unquestionably the automotive Diesel engine is not an easy problem to solve, yet the fact is that one of the great mail order houses of the country now lists regularly in its catalog a farm engine of injection type and of as little as 3 in. bore. Also at least tolerable success must have been obtained in Germany by the Junkers engine, in France by the Bellem and the Bregeras and Caffort engines, and in England by the Blackstone engine, all using injection in one form or another. We all know that the large size injection engine is a complete success. When Mr. Ricardo announces that he has completed an aeronautical engine of 8 in. bore, operating successfully at 1350 r.p.m., it would seem to me that sizes have been reached where there ought to be little difficulty in applying the injection principle. C. A. NORMAN.

Disinterested Tests Preferred to Economy Contest

Editor AUTOMOTIVE INDUSTRIES:

In an editorial of one of your recent issues you suggested that it would be advisable, as a means of arousing public interest in fuel conservation, to arrange a public competition in which different makes of cars might participate. In the writer's opinion, such a competition might arouse public interest, but its results would be harmful rather than otherwise, in that the conclusions drawn by the public from the competition would almost certainly be wrong ones.

The relative showing made by an entrant in this competition would depend upon, first, the general efficiency of the car and motor design; second, the amount of special pains taken in getting this car and motor in better condition than the average car of the same make; third, the skill of the operator and his ability to make a better showing than would the average driver; fourth, points of special adaptation which are known to increase the fuel economy but are not practical for general use.

As instances of the second item, pistons might be used with more clearance than standard; special pains might be taken in running in motors and other parts; also special spring, tire and wheel bearing equipment. An instance of the third item would be the use of a carbureter adjustment much leaner than the average driver would tolerate, requiring the use of a choke or dash adjustment each time the throttle is opened; another would be the practice of throwing off the switch and throwing out the clutch every time the speed of the car is decreased. Item No. 4 would include various means of causing the engine to operate more nearly at full load conditions at all times, either by the use of a higher gear ratio or loading the car down to increase the effort required to pull it. A similar increase in economy could be made by raising the compression to a point where it would be unsafe to open the throttle wide.

Now it is evident that in a competition involving a number of different cars it would be impossible for the most competent engineer, and far beyond the general public, to analyze the showing of a car in respect to the different points just mentioned. It should also be borne in mind that the entrants from each factory would be more keen about the advertising value to be obtained from the test than the development of scientific knowledge and it is very probable that many special points of construction, along the lines referred to above, would be kept secret.

It would seem to the writer that the desired ends would be obtained to a much greater extent if experiments or public demonstrations were conducted by a *disinterested* research committee, on a *single car or motor*, showing the relative saving of fuel possible with different methods of driving, different conditions of motor and running gear, different fuels, different temperatures of intake manifolds, compressions, gear ratios, etc. In this way accurate comparisons could be made, there would be no question as to the correctness of the conclusions reached and there would be no danger of the experiment degenerating into a mere publicity and advertising contest. F. C. MOCK.

A MEMBER of the Society of Automotive Engineers who has been instrumental in furthering standardization of truck parts has recently received from George E. Roberts, vice-president of the National City Bank, a letter from which the following extract is taken:

"We have got to look to the engineer very largely for help in our industrial troubles; that is to say the most promising solution for our troubles is in greater efficiency in the organization and equipment of industry. The work that your organization is doing in standardizing automobile parts is of great significance, and if similar work is done throughout the industries we will make substantial gains."

What of the Safety and Personnel Departments?

The widespread elimination of safety and industrial relations departments indicates that they were established as temporary measures and are not viewed as of permanent operating value. Discussing matters with the workers is not a favor, but a matter of good business and production value.

By Harry Tipper

A SURVEY was made recently of the position of safety engineering as a special occupation in many of the large industries at the present time, as compared with its position in this respect a year or so ago.

Safety engineering developed to a very considerable degree just prior to the war and during the war. A number of men were engaged in specializing in this kind of work, and a great many improvements were secured, because of the exhaustive consideration of the matter and some understanding of its relation to efficiency in operation.

A rather large bibliography grew up around this and special publications were confined to its consideration. It is a little disturbing, therefore, to find that this work has been considered as such an outside matter, that the safety engineering department has been eliminated almost entirely in a number of cases. In other instances it has been cut down to such an extent that its effectiveness is lost and it will be a difficult matter to build the organization up again.

In one case, where a concern used forty-three safety engineers, with an extensive department created for the special study of safety work, all but three of those have been eliminated, and consequently practically all the research and most of the development work has been dropped. Some of the work in this establishment consisted in bringing the safety necessity home to the worker, making him understand his responsibility in connection with the matter.

The value of this kind of discussion does not end with the safety work, yet the department is ruthlessly cut even though the engineering departments are maintained with all the key-personnel remaining on the job. Something similar has happened to the industrial relations departments in a good many plants.

The elimination of these departments is not in itself so important. In both cases they are matters which should be a part of the training of every executive and a definite part of the quality and ability demanded of them. The practical elimination of these departments, however, indicates that they were not viewed as permanent necessities of analytical and operating value. This is the disturbing feature of the case.

It is not to be expected that such departments would remain full of men in a time of low industrial activity, but the fact that they have been practically wiped out in a number of cases indicates the attitude which has been taken toward them by the responsible executives in the establishments concerned. I have no brief for the erection of such departments in the first place, although it may be necessary to put specialists upon the studies of these matters, because of the general lack of intelligence among executives regarding them. It has been my firm opinion that nothing will be secured of great moment in the analysis of the human relations within a plant, until all executives who have charge of workers and who determine the policies are required to study the human side of the question.

It is evident that a good many of these departments of safety engineering and industrial relations have been created without a sufficient analysis of the matter and without a proper understanding of their functions or their value to the establishment. This has led to their acceptance because of temporary conditions, labor shortage, difficulty of meeting labor demands, and so forth, as an extra necessity on account of these conditions and not as a fundamental branch of the business, directed to the study of important matters.

Despite the existing evidence concerning the potential capacity of the human being, over and above the actual capacity which he puts into his work, there appears to be a general disbelief in the validity of humane methods of drawing out this potential power and putting it to work.

Most executives still think discussing matters with workers is an act of generosity, a sop to the workers or a matter of so-called welfare. Comparatively few of them have considered the matter as good business and necessary to the greatest production value. When mention is made of the results achieved in an establishment where these matters have been considered seriously, the first reaction is that such establishments are different, that other establishments were unsuccessful, or that the old way is best.

It is worth while repeating at this point, several of the fundamental reasons for the study of the human side and the fundamental values which can be expected from the proper kind of co-operative effort within the plant.

(a) The number of examples we secured during the war, when the general efficiency was decreasing, showed that it was possible to secure from 50 to 125 per cent increase in production capacity from the same workers with the same machinery and operations.

In some of these plants despite 100 per cent increase in wages the labor cost per unit of production had decreased a small percentage.

None of these things were due to improved machinery or any new system of development, but almost entirely to the discussion with the workers, the consideration of the workers and the feeling of co-operation which permeated the establishment.

(b) The studies of fatigue have shown that the mental factors of fatigue exercise a more important influence upon the production pace than the physical fatigue involved. In other words, the fatigue induced by the loss of interest and incentive translates itself into a greater physical effect than the fatigue directly resulting from the physical motions. This tends to establish a minimum pace and prevents the worker from putting forward his full power in the working operation.

(c) The rate of pay per hour doesn't have any very important bearing upon the possible cost per piece. Hours have been reduced without increasing the cost, and wages have been increased without increasing the cost per piece.

The relation which is presumed to exist in most of the discussions upon this subject is incorrect and leads to many false calculations, limiting the efficiency and destroying the value of the final observation. It is somewhat amazing that so little attention should have been paid to this matter and yet the presumption that a direct relation exists between wages paid and work done runs through 90 per cent of the discussion about wages that is going on at the present time.

(d) The industrial establishment is at present utterly divided in its outlook upon production, prices, reward of capital and other matters which intimately concern all parties engaged. There is a continual warfare between the groups in industry for the establishment of their own advantage and a continual disagreement which consumes an enormous amount of time, eliminates a very large amount of useful effort and adds to the cost of every operation which is conducted in the process of getting raw materials to the point of consumption.

These are practical items. They relate to costs; they relate to the limitation of the buying power; they show a large amount of waste effort, and they add to the burden which must be supported by industry and the consumer.

Yet these are the items which can be overcome only by a study of the human side of the question. The mathematics of industry are governed by the humanities of the case and not vice versa, as we seem to expect. These practical points are of sufficient importance in their effects upon industry and of sufficient volume in their relation to total costs to warrant the most careful examination and painstaking study. Yet, while the manufacturer retains his engineering department, almost intact in many cases, he has practically eliminated the industrial relations department, the welfare division and the safety engineering.

An old business philosopher said to me many years ago regarding the practical man who argues only from experience, "The man who is limited to what he can see and practice is the most impractical business man of the lot." Certainly this is true of the executive who shuts his eyes to the importance of the human side and the study of its fundamentals and its relations.

An Elevating Dump Body

(*Continued from page* 608)

position by the hydraulic hoist, which is controlled from the driver's seat in the usual way. The release hooks are engaged, as indicated by the hand lever resting in the forward position. To illustrate the method of operation, grasp a lead pencil between the thumb and fore-finger of the left hand, at about one-third the distance from one end, and hold it in a horizontal position. With the other hand press down on the short end. If an object representing the dump body were on the long end of the pencil, it would, of course, be elevated. The thumb and forefinger of the left hand represent the pivot shaft of the main elevating lever which is supported by the elevating frame. The forefinger of the right hand pressing down on the short end of the pencil represents the pull rods pulling down on the lower end of the main elevating lever.

If it is desired to dump without elevating—that is, in the ordinary position—the release hook lever is thrown toward the rear, thereby releasing the pull rods. The hoist is then operated in the usual manner. The body resting on the elevating frame, is raised at the front end only.

The body is made with a capacity of 80 cu. ft. for soft coal, and with less capacity for other materials. The height above ground of the bottom of the body when loaded is 6 ft. The hoist has a cylinder diameter of 6 in. The elevating frame is made of rolled steel channel 6 in. deep, weighing 10½ lbs. p. ft., well braced by ¼ in. thick cross members. The total weight of the body, hoist, elevating mechanism, telescoping chutes and bagging chute is 2950 lb.

British Government Assists Aviation

THE British Cabinet has approved (subject to Parliamentary sanction) the grant of a sum for the direct assistance of civil aviation. During the financial year 1921-22, payments under this grant will be limited to a maximum sum of £60,000 and will be made to British companies operating on approved aerial routes. They will be calculated, subject to the above limitation as regards the total sum available within the year, on the basis of 25 per cent. of the total ascertained gross revenue of each company—exclusive of the Government grant—earned by the carriage of passengers, mails or goods.

The routes at present approved are London to Paris, London to Brussels, and London to Amsterdam. Extensions to these routes and additional routes, such as England-Scandinavia, on which the possibilities of a service employing flying boats or amphibian machines, or a mixed service of sea and land aircraft, can be demonstrated, may be approved from time to time if satisfactory proposals are received by the Air Council. The maximum time allowed for journeys between London and Paris, between London and Brussels, and between London and Amsterdam will be four hours from aerodrome to aerodrome, or such other time limit as may be determined later by the Air Council.

Government Helps for Business

MANY business men are holding the hope that with Herbert Hoover as Secretary of Commerce there will be a decided change for the better in the matter of appropriations for this department which means so much to the business world. Especially hopeful are those who are interested in export trade.

During consideration of the recent appropriations bill it was shown that the amount set aside for the Bureau of Foreign and Domestic Commerce was less than one-fiftieth of one per cent of the total appropriations for the Government. Secretary Hoover should be able to secure an increased proportion of the total to be voted in new appropriation bills. The business men of the country will certainly support him in such a request.

They appreciate the need for economy in government expenses, but are not committed to any policy which precludes expenditures, the results of which promise so much benefit as will result from a well-organized and intelligently operated Bureau of Foreign and Domestic Commerce.

Movable Track Automobiles

THE chain track principle was introduced in connection with heavy tractors that are required to pass over soft ground and through boggy places, the earliest application (or intended application) of this mechanism probably having been in connection with artillery haulage. During the war the chain track vehicle became widely known through its use for tanks and artillery tractors. In peaceful applications the outstanding feature of the chain track vehicle is that it can pass over soft, marshy ground where even a horse cannot obtain a footing, and where the use of ordinary wheeled vehicles would be entirely out of the question.

At the present time, a very large proportion of our road transportation is by motor vehicles, but there are two conditions of American country roads under which these vehicles are practically useless—when the roads are heavily covered with snow in winter and when they are deep with mud in February, March and April. It is quite possible that the movable track will help in overcoming this difficulty. Such a track for a light vehicle will probably have to be made of fabric belting, because a metal chain track would be too noisy, and if used in mud, would be subject to much wear. Naturally a vehicle equipped with such a track could not travel at the same speed as an ordinary wheeled vehicle on hard roads, but this would not be necessary. As both snow and mud are temporary conditions, it would not pay to build vehicles specially to run only on movable tracks, but the proposition of constructing tracks adaptable to standard automobiles looks promising. In a snow contest recently held in France, a car fitted with such a track was conspicuously successful, and a portable track for use on Ford cars has been developed in this country and is undergoing tests.

We have been building hard roads quite rapidly during the past ten years, but there is still an enormous mileage of roads in the country which are practically impassable for several months of the year. If some simple and relatively inexpensive attachment can be developed which will enable the ordinary automobile to negotiate any road at any time of the year, it will evidently add immensely to the practical value of cars which must in some way meet this condition.

The Elusive Saturation Point

EVIDENCE accumulates that ambitious statisticians are again turning to the problem of the "saturation point" of automotive vehicles. This is probably due to disappointment on the part of those who predicted evil days were ahead of the industry when the partial shutdown of automotive factories took place last fall. So many persons did not realize that factories making articles that had been regarded as necessities for years were also shut down—stockings, for instance. Now that the automotive indus-

try bids fair to be on high speed before some other industries, these prophets are seeking another basis for pointing out to our industry the exact location of its untimely grave.

Such prophets overlook the history of "saturation point" statistics. So many "saturation points" have been passed that they might be compared with the water that runs under the bridge. It does not appear to these persons that an automotive vehicle stands for transportation; that transportation is a part of civilization and that as long as civilization advances, transportation must advance with it. Railroad saturation probably will be reached first, because the automotive vehicle is an assistant to the railroad. Neither of these units of transportation will reach a saturation point until they are replaced by a better means of transportation.

There was a popular play in New York this winter called "Not So Long Ago." It was a violent reminder of how few years ago the "stationary bath tub" was the subject of discussion. This now more or less universal article of household equipment was then called "immoral" by some of its critics. At the same time the bicycle was making its appearance. How bitterly it was denounced! To-day the bath tub and bicycle industries are greater and more substantial than ever before. Both have a set place in every day life and scoffers of "not so long ago" must admit their error.

Passenger Car Body Standards

THE need for standardization of passenger car body parts would appear to be quite as important as similar work in connection with chassis parts, yet there seems to have been nothing accomplished in this direction in spite of the fact that great benefits have resulted from similar efforts relating to other parts of the car. This situation is, perhaps, due to the fact that body engineering has not kept pace with other branches of automotive engineering, while much body construction is still carried out according to old-fashioned methods used in carriage building.

Under these circumstances the first meeting of the Passenger Car Body Division of the S. A. E. Standards Committee held in New York last week can be regarded as marking a new epoch in the body industry. The new division does not, of course, expect to standardize any one design or group of body designs, nor does it plan or hope to fix dimensions that will limit initiative or prevent originality on the part of the designer. It may ultimately prove possible to agree upon certain dimensions that will facilitate in some measure interchangeability as between body and chassis of approximately the same size and type—as is already being planned by the Truck Division in connection with truck bodies—but for the present the committee plans to confine its work to standardization of body parts, hardware and materials, in some cases simply setting down for reference purposes practice which is now more or less generally followed.

Among the items which will probably receive consideration on the part of the division at an early date are: Top irons, window runways, size and thickness of glass, door handle square shank and hole, gage sizes for sheet metals, dimensions of stock shapes and mouldings, wire sizes for fender beading, nickel plating standard, door hinges (pressed and malleable), standards for leather and top materials. If the division is able to make progress in the development of these standards, that alone will amply justify its organization, yet these items represent only a very small part of what can and no doubt will finally be done.

The division as now constituted includes representatives of five body manufacturers, five car manufacturers who build their own bodies, one manufacturer who builds both bodies and chassis as well as bodies for other chassis builders (some of these being custom bodies), one body parts manufacturer and one consulting body engineer. Only six of the thirteen members attended the first meeting of the division. It is to be hoped that later meetings will be better attended, for the industry will watch the work of the division with interest and expect much from it. It should, and we believe it will receive the hearty support of all whose co-operation is sought.

Disrupting a Tax Policy

AN indication that the National Automobile Chamber of Commerce was wise in eliminating details from the tax program appears in a recent report of a ballot by the members of the Chamber of Commerce of the United States, which always carried its projects to the last possible detail.

One of the points of this ballot was a sales tax. The idea was defeated. Next came a ballot on the kinds of a sales tax. Even those persons who voted against the sales tax voted on this detail, and three sorts of sales tax had about equal support.

The hopelessness of developing a tax theory that will be supported by the membership of the Chamber after this division is evident. These are details that the N. A. C. C. plan will leave to the technical tax workers.

Ways and Means

DURING this period of readjustment when wage decreases are common, it is very interesting to follow the reaction of the workers in specific cases, and to attempt to analyze the reasons for that reaction in any given instance.

There are already numerous cases on record in which wage reductions have been met by a strike or by a strong protest of some kind. In a few cases, however, the readjustment has been made without difficulty, the employees shop committees even voluntarily making the reduction in one or two instances.

The way in which the management went about making the reductions undoubtedly had much to do with the reaction on the part of the workers. Those firms which have taken the trouble to consult, explain and reason have had by far the best success. No man can be expected to enjoy having his income decreased, but it is possible for him to be "sold" on the temporary necessity for it. And if he is to be retained as an employee he must be "sold" or his work will not be permanently efficient.

Ford Operating on Own Resources

Bank Loan Deferred, May Not Be Needed

Rapid Turnover of Surplus Cars and Inventory Helps Finance Factory Operation

DETROIT, March 14.—The Ford Motor Co. to-day is employing more than 20,000 men turning out around 3,000 cars a day, and is "going it alone" so far as finances are concerned. AUTOMOTIVE INDUSTRIES is able to say positively that Henry Ford is not seeking financial assistance, and for the time being at least, is operating successfully without it.

Just how long the company will be able to continue operation without financial help is a matter of conjecture, though it is reasonably certain that the company will ask for a bank loan about the middle of April when the thirty-day extension period granted the Ford Company by the Government for the payment of the first installment of taxes will have expired. That this money will be available without any delay or controversy also is certain.

The facts in the Ford financial situation are as follows: In January Henry Ford sent to New York for a representative of the New York bankers to come to Detroit to discuss finances. This representative came and the situation was gone over thoroughly. The banker suggested that Ford would need about $50,000,000. Edsel Ford, however, was of the opinion $75,000,000 would be required.

Ford Men Satisfactory

The hitch came when, as the climax of negotiations the banker set forth conditions upon which the loan would be made, among which was the stipulation that a treasurer must be installed to succeed F. L. Klingensmith, who would be satisfactory to the bankers. Henry Ford was asked to name three men which he did, one of whom was W. R. Campbell of the Canadian Ford plant. The bank representative scratched out the name of one man but announced that either Campbell or the third man would be all right. Campbell at that time came over to the Ford plant and remained for more than a month, and it was presumed he would be made treasurer, though he finally has determined not to join the organization.

With the matter of the treasurership settled, it looked as though the loan would be made, but Henry Ford balked at one other condition set forth and refused to accept the loan with this other stipulation included. He expressed the determination to go ahead with production without financial help, and the bank representative advised him that he felt confident Ford under the circumstances could do this successfully. The proposition of placing the plant under bank control, rumored as the stumbling block, was not touched upon.

Debt Reduced to $24,000,000

This advice was given in view of the fact that Ford had reduced his indebtedness to around $24,000,000 by the conversion of Liberty Bonds, which had been deposited as collateral to secure that loan. The further fact that Ford cars were selling steadily and that the company was reducing its inventories at a good rate, prompted the banker to offer his suggestion that it would be possible for Ford to operate without financial help at least until this bank indebtedness became due together with the Government taxes.

In other words, the proposition was put to Ford exactly this way: His obligations with the extension of time granted by the Government would not become due until the middle of April. It was possible for him to operate until that time without financial help. It was also possible that he might meanwhile, through extraordinary sales demand, be enabled to make whatever settlement became necessary the middle of April without asking for aid at that time. In the event, however, that bankers holding Ford notes insisted upon payment when those notes became due again at the same time the Government taxes were payable, Ford could have at his command as much money as he wanted from the banks on the condition they imposed. He could run until his last dollar but always had the knowledge that a telegram would bring him any money needed.

Interest at 8½ Per Cent

The loan sought in January and the loan that will be made in April—if it is made—was to be and will be at 8½ per cent gross, considered by bankers to be very reasonable. During the negotiations Henry Ford and his son Edsel agreed that they would not take any dividends pending the life of the loan, volunteering this to the banks' representative.

The bank indebtedness against the Ford Motor Co. represents notes upon which renewals have been asked five times, it is reported. It also is said with reasonable assurance that a sixth renewal on a majority of these notes will

(*Continued on page* 632)

Ford Treasurership Is Left Unfilled

Campbell Declines Position—To Continue with Canadian Company—Co-ordinate Work

DETROIT, March 11—Considerable interest has been aroused in the future of the Ford organization by the fact that W. R. Campbell of the Ford Motor Co. of Canada finally and definitely has refused to become associated with the American organization. Campbell was sent for by Henry Ford soon after the resignation of F. L. Klingensmith as general manager, and it is said Ford offered him the position vacated by Klingensmith. Campbell was reluctant to leave his Canadian post, but Ford urged him so strongly that Campbell remained at the Highland Park plant from the time of the reopening until last week virtually in charge of the organization there.

It was unofficially stated at Highland Park three weeks ago that Campbell had finally declined to become general manager, but would accept the office of treasurer. In fact, Campbell himself admitted he had finally refused to become general manager and virtually admitted he would accept the treasurership.

What developed to cause Campbell to change his mind is not known. Close friends quote him as saying he had seen too many bigger and better men than himself summarily dismissed or forced to resign for disagreement on company policy and did not "intend to go along with the procession."

At present Ford himself is said to be in active charge at Highland Park as well as the River Rouge plant, where tractor production was started two weeks ago. C. E. Sorensen, who has held the title of general manager of Henry Ford & Son, divides his time between River Rouge and Highland Park and virtually is looked upon as General Manager of Ford properties.

Kanzler Heads Production

Since the resignation of W. G. Knudsen, E. C. Kanzler has been in charge of production at Highland Park. However, the title of production manager has not been conferred on Kanzler, and Ford recently intimated it was his intention to eliminate titles and co-ordinate the work of the various departments with direct control of the big organization centered in the group of executives headed by himself and including Edsel, Sorensen, E. G. Liebolt, Ford's private secretary; W. A. Ryan, general manager; B. J. Craig, secretary; Fred Diehl, purchasing agent, and Kanzler.

Hoover Makes Foreign Trade Plans

Standardization Aim to Be Important One

Reduction of Wheel Sizes One of First Suggestions Expected—Stresses Economy

WASHINGTON, March 11—Standardization of automobile wheels will be suggested to the automotive industry by the Department of Commerce as part of a nation-wide movement toward standardization of manufactured products. In reorganizing the Department of Commerce for improved efficiency to business, Herbert C. Hoover, the new Secretary, contemplates extension of Government co-operation with trades and industry for the promotion of foreign trade against other competitors. The Government will in no way force regulation but will endeavor to accomplish its aim by proof of necessity and then by co-operation with industries.

Secretary Hoover is convinced that foreign governments are mobilizing the export trades, and in some cases the import, for militant commercial invasion. His studies abroad showed him that foreign merchants are obtaining support of their governments in pooling which will decrease manufacturing and distribution costs. This governmental assistance or even subsidy allows the European manufacturers to compete with American exporters at home and abroad.

In his first interview with Washington correspondents since assuming the Cabinet portfolio the Secretary cited automobile wheels as an instance where standardization would prove effective. He said that it was possible to cater to the needs of the automobile users by reducing the number of wheel sizes from 11 to 4. Secretary Hoover contended that this reduction in models would automatically reduce the expense of keeping rubber stocks by half. He asserted that the experiences of the war had demonstrated the necessity for standardization and its economies.

Lower Costs Imperative

American manufacturers must lessen production and distribution costs immediately if they are to preserve their standing on foreign markets, the Secretary says, because the tariff would only protect against invasion of domestic markets and have no effect on competition abroad. He contends that every ounce of efficiency is needed for American industry to recuperate and extend its markets abroad.

Hoover's interest in standardization of automobile wheels would indicate that he will encourage the research activities of the Bureau of Standards which is under his supervision. This Federal agency has made numerous investigations relating to standards in the automotive trade but failure of Congress to provide additional funds has somewhat checked its work. It is believed that with a national movement for standardization, it would be an easy matter for Secretary Hoover to obtain special or deficiency appropriations for whatever scientific inquiry the Bureau might undertake.

The question of economies of distribution will undoubtedly be stressed in all branches of business. It is here where the economies of highway transportation will be demonstrated, for shippers are desirous of relief from rail-hauls.

Statistical Division to Undergo Change

WASHINGTON, March 15—Automotive trade associations and individual exporters will be consulted shortly by a special committee appointed to-day by Secretary of Commerce Hoover, to reorganize and revise the methods used by the statistical division of the Bureau of Foreign and Domestic Commerce. Numerous complaints have been received as to discrepancies in export and import statistics and suggestions will be studied.

Exporters of automobiles, trucks and tires have manifested unusual interest in foreign trade statistics of late in order to gage the condition of foreign markets and the revival of competition. Manufacturers have complained to the secretary that there were numerous discrepancies in the figures prepared by the Bureau of Foreign and Domestic Commerce for August. Inquiry developed the fact that customs officials were overburdened and omitted certain items for that month. This error makes the official figures on all commodities open to question.

The committee, headed by William S. Rossiter of Concord, N. H., will conduct an inquiry into this mistake and revise the records.

The blunder in compiling official statistics sheds light on the failure of the Department of Commerce to publish data within a reasonable period. It is stated that errors are incidental to decoding and preparation for publication of reports from the collector of customs at New York.

Suggest New York Location

The small appropriation makes it impossible for the bureau here to furnish manufacturers with information and this import material is prepared by underpaid, and in many instances, inefficient clerks. It has been suggested that the statistical division have headquarters in New York.

Will Seek Enactment of Favorable Bills

Lower Rail Rates to Seaboard Important—Would Erect American Warehouses

WASHINGTON, March 15—Secretary of Commerce Hoover has indicated his intention to promote foreign trade in automotive products and other commodities on a gigantic scale. There is reason to believe that he will urge upon the new Congress legislative measures which will aid the movement and sale of American products on foreign markets. It is understood that he will recommend the liberalization of the Webb-Pomerene and Edge acts, lower freight rates to the seaboard and equitable ocean rates, establishment of American banking agencies abroad and erection of American warehouses at the principal foreign ports.

Business men, principally manufacturers, have complained to the new Secretary of Commerce that the rail traffic will not bear the present freight rates. He has been advised that the industrial centers of the country will be moved unless relief is accorded in transportation rates. Traffic experts believe that the commercial map will be changed by the removal of industries toward the seaboard, so that the rail haul will be relatively short. If the railroads do not lower their rates it is believed that shippers will turn to a more extensive use of trucks and waterways, which provide cheaper transportation.

The establishment of warehouses in foreign countries is regarded as essential to the success of American foreign trade. It is known that British and German traders own or control warehouses to-day in countries where American exporters are cultivating trade. Though American goods are stored in these places, it is known that the owners would naturally endeavor to dispose of goods manufactured in their countries which compete with American products.

Discrimination Hurts Trade

The Department of Commerce has a plan under consideration which would to a large extent prevent this discrimination against Americans. Warehouses constructed by the Government and in charge of consuls or other Federal agents would undoubtedly help American traders. There is also a proposal to extend branches of the Federal Reserve system at the principal ports.

In suggesting standardization of automobile wheels, Hoover made it clear that his proposals for standardization in all industries were made to allow more effective competition on foreign markets.

Durant-DuPont Deal Disclosed in Report

G. M. C. Holdings Taken Over for $23,790,600 in Cash and Stock Consideration

NEW YORK, March 14—Details, hitherto carefully concealed, of the spectacular financial transaction by which W. C. Durant retired almost over night as head of the General Motors Corp., are disclosed in the annual report of E. I. duPont de Nemours & Co. It shows that when Durant was unable to meet his obligations last November, the duPont Securities Corp. took over 2,504,273 shares of General Motors stock. He received for his holdings $23,790,600 in cash and 40,000 shares of the stock of the Securities corporation which was formed to buy his General Motors stock.

It is stated in the report that the taking over of the stock was at the request of Durant, who had informed the duPont interest that "he desired to resign and sell his interest in the corporation to liquidate his personal indebtedness, which was very large and pressing."

On the basis of the amount of money paid to Durant it is figured that he received $9.50 per share in cash for his General Motors holdings. The 40,000 shares of stock of the duPont Securities Corp., it is stated, have since been exchanged for 230,000 shares of General Motors common stock, which again gives him a substantial holding in the concern. If a value of $13 per share were placed on this amount of stock it would add $2,990,000 to what Durant received for his original holdings and would bring the amount up to about $10.70 a share.

At the time of the transaction there was much speculation in Wall Street as to just what amount was involved in the exchange. Estimates made at the time placed the amount at $27,000,000, but it was also gossiped around the Street that Durant received only between $7 and $9 a share.

Show Details of Financing

The financing of the transaction whereby the stock was taken, it was pointed out, was by the sale of $20,000,000 one-year 8 per cent collateral trust bonds of the duPont Securities Corp. through J. P. Morgan & Co. These bonds fall due on Nov. 22 of this year, but in consequence of this maturity the report states that the officers "are now working on plans for the permanent financing of this additional investment on the General Motors Corp., the details of which plan will be communicated to the stockholders as soon as completed."

In addition to the notes sold through the banking firm, the duPont American Industries Co., the stock of which is 100 per cent owned by the E. I. duPont de Nemours Co., paid into the treasury of the duPont Securities Co. $4,200,000 in cash and loaned 824,179 shares of General Motors, for which it received $4,200,000 in shares of the 8 per cent cumulative preferred stock and 36,000 shares of the non-voting common stock of the new company. The Chevrolet Co. paid $2,800,000 in cash and loaned $549,453 in shares of General Motors, receiving $2,800,000 preferred and 24,000 shares of the common stock of the duPont Securities Corp.

Obtained 4,000,000 Shares

By this method, it was also pointed out, the duPont Securities Corp. obtained $27,000,000 in cash and borrowed 1,373,632 shares of General Motors common stock. This stock, with the 2,626,368 shares taken over from Durant, gave the duPont Securities 4,000,000 shares of General Motors, which was pledged with the bankers for the $20,000,000 loan. It is also stated that the banking group received 20,000 shares of the common stock of the duPont Securities Co. as a commission for the loan. This was paid out of the 60,000 shares received by the duPont American Industries and the Chevrolet Co.

The report also states that under the same transaction with Durant the duPont Securities Corp. took over 122,095 shares of General Motors common from a syndicate consisting of the duPont, the Chevrolet companies and Durant. For this stock they paid $2,163,557 cash, which was the equivalent of $17.72 a share. This stock, however, has since been sold.

Durant Not Seeking Studebaker Control

NEW YORK, March 14—Formal denial has been made by W. C. Durant that he is seeking control of the Studebaker Corp. to make it the nucleus for Durant Motors, Inc. The reports became current when Durant bought a large amount of Studebaker stock in the market.

STUDENTS TO VISIT PLANTS

PHILADELPHIA, March 11—Twenty-seven seniors of the Mechanical Engineering School of the University of Pennsylvania have left here on an extensive tour through the Middle West. This will include a trip to the new factory building of the Cadillac Motor Car Co. of Detroit. The men are accompanied by Prof. R. H. Fernald, of the mechanical engineering department. They will inspect plants in Pittsburgh, Chicago and St. Louis.

PUBLICITY BRINGS BUYERS

DAVENPORT, IOWA, March 12—Automobile dealers in this community report a 50 per cent increase in trade within the last week. An early spring and an active publicity campaign which took the place of the usual automobile show were responsible for the revival, they said. No adequate exhibit room could be secured and the dealers went into an aggressive publicity campaign.

Indications are that the season will be a record one, some dealers said, and all of them have felt a business revival which has drawn expression of surprise.

Maxwell Defends Chalmers Merger

Asks Dismissal of Partition Suit Filed in Wilmington—Fixes Valuation

WILMINGTON, DEL., March 11—An answer has been filed in the United States District Court to the suit of Charles J. True against Maxwell Motor Co., Inc., by Carl Tucker the vice-president.

He claims numerous errors in the bill of complaint. Special stress is laid upon the fact that the book value of the stock of the defendant corporation, stated at $22,117,230.80 as of Dec. 2, 1920, is liable to deductions for reserves for depreciation, contingent liabilities aggregating $4,513,265.80, and furthermore that said book value, approximately $134 per share on the outstanding first preferred stock, is largely dependent on the defendant being a going concern.

Excepting the amount of the aggregate tangible assets of the Chalmers Motor Corp. these are asserted to have had the value on Dec. 2, 1920 of $4,519,722.57 and not $435,014.02 as alleged in the complaint.

It is admitted that a meeting of stockholders called to be held in this city on or about Oct. 19, 1920, has been adjourned from time to time, and has never been held, but proof is demanded that a properly accredited representative of the plaintiff was appointed to attend this meeting, and holds that the cause of the adjournment of the meeting was the failure of the defendant to receive a sufficient number of proxies to constitute a quorum.

It is admitted that the bill of complaint filed on Jan. 14, 1920, in the District Court for the southern district of Michigan, as well as others in Indiana and Ohio, was filed for the purpose of averting the danger of judgments, levies, etc., substantially all of the property of the defendant being located in these three states, the courts assuming jurisdiction and control of the assets.

It is denied that the equity in defendant's property is sufficient to provide for the full value of the plaintiff's stock and that of other first preferred creditors in case the property of the defendant is liquidated. The dismissal of the bill of complaint is asked.

A petition for leave to intervene in the suit has been filed by Robert W. Seaton of New York, owner of 200 shares of first preferred stock of Maxwell Motor Co.

ELECTRICAL SCHOOL FORMED

MILWAUKEE, March 14—The School of Automotive Electricity of Milwaukee has been incorporated with a capital stock of $100,000 as a development of the department established about two years ago by the School of Engineering of Milwaukee to train specialists in automotive electrical engineering.

Firestone Business Reaches 60 Per Cent.

Starts Second Shift on New Production Schedule—Surplus Nearly Exhausted

AKRON, March 12—Although directors of the Firestone Tire & Rubber Co. of Akron voted under date of March 15 to pass the common stock regular quarterly dividend due March 20, the company lists a surplus of approximately $33,000,000 and states that it has more than $7,500,000 in cash in bank.

The Firestone statement, issued in connection with the dividend action of directors, is one of the most optimistic issued by any rubber company in Akron since the beginning of the tire industry slump last May. The company is now producing about 7000 tires daily, and is operating five days a week with full eight-hour days. It is one of the first Akron tire concerns to reinstate the second shift, and is now operating two eight-hour shifts on tire production. The second and third shifts were dropped when the low ebb of the tire industry slump caused all Akron concerns to retrench and to reduce production to less than 25 per cent of normal.

Firestone reports that its surplus stock of tires is almost exhausted and that increased production is necessary to replenish these stocks, due to the rapid increase of tire sales. For the first ten days of March the company's business took a decided spurt, sufficient to warrant the official prediction by President H. S. Firestone that his company would do business in excess of $6,000,000 in March. The company's sales for the past fiscal year were $114,980,969, as compared to $91,078,513. Figuring on this basis, Firestone is now doing nearly 60 per cent of its average monthly business of last year. This is perhaps a higher percentage of respective normal business than is being done by any Akron tire company at the present time.

In addition to being one of the first to re-establish the second shift, Firestone is also the first Akron tire concern to begin re-employing men. During the past few days several hundred men have been taken on. Great care is being exercised by the employment division, however, in picking from the many applicants those formerly employed by the company, with preference shown to married men and to men on record as the company's former most efficient workers.

Miller Stocks Run Low

The Firestone prediction of a shortage of tires is strongly corroborated by recent action of the Miller Rubber Co. of Akron in calling in all available supplies of tires from districts where sales have been slow, in order to rush such stocks to points where sales are increasing rapidly. This action will preclude necessity, for the time being at least, of materially increasing production.

The Goodyear Tire & Rubber Co. has just increased production from 35,000 tires to 60,000 weekly, which is slightly less than one-third of peak production. Whether the company puts on any great number of men will depend largely upon the successful consummation of the company's refinancing program involving $85,000,000.

Business Renewals

Detroit—Property of Adrian Tractor Co. at Adrian, Mich., has been attached by several concerns holding claims for construction material. The Adrian Tractor Co. was formed last fall, and a sale of stock to secure funds for the construction and operation of a factory was begun but was stopped by the industrial depression.

Detroit—Columbia Body Co., which builds commercial bodies and truck cabs, has purchased a new plant containing 40,000 feet at Ford City, Mich. Increased business of the company and orders in prospect necessitated the expansion, officials say, and as quickly as the plant can be put into production, between 150 and 200 men will be employed.

Detroit—Erdman-Guider Co. officials announce receipt of an order for a large number of bodies for the Sheridan unit of the General Motors Corp. The bodies are constructed in Saginaw and painted and trimmed in the local plants. Company officials say indications are that the company would require an output of 5000 bodies this year.

Sheboygan Falls, Wis., March 14—The Falls Motors Corp. has increased its working force to nearly 400, and is now on a regular operating schedule of 9 hours a day, after running on a greatly reduced schedule since Oct. 1, 1920. The normal force is about 700 men. During the reduction of operations the engineering staff erected and equipped a new testing room with a capacity of 300 engines a day and otherwise improved the plant to increase efficiency to the utmost degree. The company builds 95 per cent of the parts entering into the construction of Falls motors.

TO BUILD HIGHWAY TRACTOR

FOND DU LAC, WIS., March 14—The Bull Dog Tractor Co., originally organized at Oshkosh, but later moved to Fond du Lac, has completed the first unit of its new plant. The company will build tractors for general purposes, but will specialize in machines designed especially for highway construction, and accordingly has named the machine the Hi-Way Locomotive. It has made excellent connections with concerns building road building apparatus without power units. The design also embodies a power operated from the driver's seat for stump-pulling, removing cumbersome obstructions, moving buildings, and many other uses where power is required.

Dunlop Production to Start April 15

Plant Will Employ 7000 Men by Jan. 1, 1922—Company's Finances Arranged

BUFFALO, March 14—Production of tires at the River Road plant of the Dunlop Tire & Rubber Corp. of America will be started April 15. Nearly 7000 men will be employed at the plant by Jan. 1, 1922, of whom 99 per cent will be from Buffalo.

R. W. Snow, legal advisor of the company, made the announcement to-day before Chairman Charles B. Hill, of the Up-state Public Service Commission, when the counsel for the tire company urged that the International Railway Co. should be allowed to extend its River Road tracks to give transportation to the men employed by the company.

P. D. Saylor, vice-president of the company, said that an office force had been organized and is at work and that a small working crew is on the job cleaning up and making ready for the resumption of activity.

It is planned to start manufacture this spring and to finish up the construction work. Saylor said that the key men of the organization have been retained and that all will be in readiness when the time comes for resumption.

Construction work at the Dunlop plant was suspended the first of the year and nearly the entire staff and corps of men which had been built up during 1920 was taken off. It is understood the company has now arranged its finances and is ready to start operations.

Public Fails to Buy Dunlop Stock Issue

(*By Cable to* AUTOMOTIVE INDUSTRIES)

LONDON, March 12—Underwriters of the new $15,000,000 issue of first debenture stock of the Dunlop Rubber Co., Ltd., have been left with 73½ per cent of the issue on their hands. The public subscription amounted to only $3,750,000. In spite of this result, however, Dunlop stock is quoted higher on the market.

Rolls-Royce will pay dividends of 10 per cent this year as compared with 15 per cent last year. The net earnings amounted to $963,885, or about the same as last year, but the directors decided to reduce the dividend rate because of conditions in the automotive industry.

CHARLES G. STODDARD DIES

NEW YORK, March 12—Charles G. Stoddard, who with his brother founded the Stoddard-Dayton Automobile Co. and later became vice-president of the United States Motors Co., died yesterday at Galveston, Texas, aged fifty-seven. He was born in Dayton, was graduated from Princeton, and retired from business recently because of ill health.

Rail Strike Threat Brings Truck Call

Council of National Defense Makes Plans for Mobilizing Motorized Transport

WASHINGTON, March 14—Serious thought is being given by the administration to the possibility of a general railroad strike as a result of the announcement by nearly all roads that the wages of all classes of employees will be drastically cut in the interest of economy and in the hope that lower freight rates can be given to stimulate business.

Unofficial but none the less authoritative information has reached the White House that if the pay of their members is reduced, the four great brotherhoods will advocate a strike in opposition to such a program. While it is the general belief that if there were such a strike it would be of brief duration, the Council of National Defense is preparing for a mobilization of the motorized transport to prevent suffering and economic disaster throughout the country. It is known that the council has devised a plan for the allocation of motor trucks. This program is based upon concrete data already in its possession and from State legislation lists.

The council will not assume control of highway transport unless it is evidenced that the railroads are unable to function properly. The council is dependent largely upon the co-operation of the State executives for the organization of volunteer motor truck associations at strategic points at centers of population.

In the last transport crisis when the brotherhoods threatened to quit, the Council of National Defense asked the various governors to obtain data as to the character, capacity, ownership and location of motor trucks throughout the State. The governors in turn addressed communications to the municipal authorities asking for their co-operation in obtaining pledge cars from direct owners in the local zones.

Congress Action Harmful

The failure of Congress to provide appropriations for the maintenance of the Council of National Defense has handicapped this organization in completing a survey of trucks and other forms of highway transportation, which they regarded as essential to the nation's safety. The council now maintains a skeleton organization for the purpose of rounding out its affairs before the end of the present fiscal year. In the event of a national crisis in transportation there is but little doubt that Congress would authorize additional expenditures in this direction.

Communicaions received from governors show that in the majority of States, at least, it will be an easy matter to organize an efficient transportation system over the highways. The Federal Government, however, is not prepared to render assistance in highway transportation in any such proportion as heretotofore. The depletion of War Department trucks through sales has been rapid during the past year.

According to Army officials there are 19,000 trucks which are available for army purposes. Out of this total 13,000 trucks are in active service with the military service. The other 6000 machines could be placed on the road for service on receipt of an order from the Secretary of War. The Secretary of War is the chairman of the Council of National Defense. The War Department had approximately 40,000 serviceable trucks and cars a year ago.

N.A.C.C. Starts Survey of Truck Mobilization

NEW YORK, March 12—A survey on the mobilization of motor trucks has been undertaken by the truck committee of the National Automobile Commercial Club. The information gathered will include the number of trucks operating in each city, their ton mileage and the type of service in which they are employed. This information is expected to enable manufacturers to estimate more accurately potential truck markets. The survey undertaken to determine the number of motor trucks on farms is about half completed.

Governor Miller of New York has announced his intention of appointing a highway transport committee. Its membership will include state officers whose duties include the development of good roads and citizens interested in the same subject.

Whittaker Takes Charge of Truck Sales Managers

DETROIT, March 14—Don F. Whittaker has been elected executive secretary of the National Association of Motor Truck Sales Managers and has assumed charge of the association affairs at headquarters, 1157 Book Building.

Whittaker has been in the motor truck business for several years with the Federal Motor Truck Co. and the Acason Motor Truck Co. He was a charter member of the association and has been active in its work.

Homer Hilton, who has been managing director of the association, has become vice-president and general sales manager of the Winther Motor Truck Co.

The next directors' meeting of the association will be held here March 25. Definite action will be taken toward furthering of plans for 1921 under Whittaker's jurisdiction.

JOHN D. DODGE WINS BEQUEST

DETROIT, March 15—Settlement out of court of the contest instituted by John Duval Dodge to break the will of his father, John F. Dodge, automobile manufacturer, was announced here today. Young Dodge, bequeathed an annuity of approximately $1,500, is to receive $2,000.000 of the estate, estimated at $80 000,000.

N. Y. Central Tries Truck Experiment

Special Equipment to Try Store-Door Delivery Plan in Western Cities

NEW YORK, March 12—An interesting experiment in the store-door delivery of express matter will be undertaken this week by the New York Central Railroad Co. in co-operation with the American Railway Express Co. The plan will be put in operation first in Chicago and Cleveland and standardized trucks will be used in its development.

A. H. Smith, president of the New York Central, has been much impressed with the possibilities of the motor truck as an auxiliary to the railroad. After careful consideration of the subject, his engineers recommended the construction of special express cars which would carry nine steel containers uniform in size which could be loaded from the trucks at the point of origin and unloaded to trucks at the destination.

The trucks will be driven to the point where the merchandise is to be loaded and then to the railroad yards, where the containers will be hoisted onto the specially constructed cars. When the destination is reached, cranes will lift the containers to the trucks and the merchandise will be delivered directly to the establishments of the consignees.

Each container will be 9 x 6 ft. and will have a capacity of 6000 lb. It is estimated that the cars which will carry them can be loaded and unloaded in 40 minutes. The New York Central is paying the expense of the experiment and is providing the standardized trucks which are to be used. If the plan proves as successful as is expected it will be extended to the main shipping points on the New York Central system.

RENEW TRUCK RATE REQUEST

NEW YORK, March 12—The traffic department of the National Automobile Chamber of Commerce has renewed its application to the Western Classification Committee for second class freight rates on motor trucks in carload lots and on chassis. The difference between first and second class rates on carload shipments of motor trucks to such western points as Denver, Kansas City, Omaha, and Dallas amounts to from $40 to $80 and more a car.

NEW ENGLAND GETS REOS

HARTFORD, March 15—Russell P. Taber, Inc., Hartford Reo distributor, finds business so good that it is necessary to receive cars by the trainload. There is now in transit from the Reo factory to the Hartford dealer a trainload of Reos made up as follows: 36 speed wagons, 34 touring cars, 10 roadsters, 8 sedans and four coupes. This big shipment is in addition to the regular February allotment of 50 cars which were all sold.

Urge Use of Trucks in Harbor Project

Engineers Would Cut Time and Expense from New York Development Cost

NEW YORK, March 12—The New York Chapter of the American Society of Mechanical Engineers has gone on record in favor of the use of motor trucks for the pretentious harbor development project undertaken by the New York and New Jersey Port and Harbor Commission. The alternative plan suggested by B. F. Cresson, chief engineer of the commission, is the construction of an electrically operated subway system extending all the way around the port through which loaded freight cars would be sent, with distribution points for rapid loading and unloading. It is estimated that such a subway would cost $280,000,000.

The engineers have taken the position that the same work could be done by motor trucks at only a fraction of the cost and no serious engineering difficulties would be involved in their use.

Motor truck interests are deeply interested in the project and their chief advocate is B. F. Fitch, president of the Motor Terminals Co. of Cleveland, Cincinnati and Chicago. Fitch also heads a similar company which has been incorporated in New York. His views on the subject were presented to the mechanical engineers and he now is seeking to win the support of the Harbor Commission, although Cresson is in disagreement with him.

It is the contention of Fitch that the use of motor trucks for such work would not be in any sense experimental and that development of the harbor in this way would consume only a fraction of the time required for the construction of a subway. He also asserts that the cost of operation would be considerably lighter. If the use of trucks is decided upon, thousands of them would be required for the work.

LA CROSSE GETS SITE OFFER

OSHKOSH, WIS., March 14—The industrial committee of the Oshkosh Association of Commerce has undertaken a campaign to secure the removal of the plant and headquarters of the LaCrosse Tractor Co., LaCrosse, Wis., to Oshkosh. It is proposed to organize a new corporation with $2,000,000 capital. The LaCrosse interests are said to be willing to invest one-half, and Oshkosh capital will absorb the remainder. A free site has been offered and arrangements made for the construction of a plant with a floor space of 80,000 sq. ft. A first year output of 3000 machines with a force of 750 to 800 workmen is planned.

The project has been under consideration for more than three months, it is stated, but no public announcement has been made until now, when Oshkosh bankers and business men have been definitely assured of adequate financing.

DELAWARE TRUCK BILL WOULD CHECK RATES

DOVER, DEL., March 14—There is pending before the Delaware legislature, now in session, a resolution the object of which is a nation-wide move to have State governments regulate motor truck freight rates. It was introduced a few days ago by Senator Bennett, who lives in the lower part of the state. After reciting the fact that every increase in railroad rates is likely to be followed by increased truck freight charges, it calls upon Governor Denney of Delaware to ask other governors to confer with him relative to the matter of having the states regulate rates.

The resolution has been referred to a committee, where it probably will lie until the time is considered ripe to bring it out and air it.

Car Makers Increase Demand for Engines

MILWAUKEE, March 12—Schedules have been released by the Wisconsin Motor Mfg. Co., manufacturer of the Wisconsin engine, to the extent of 25 engines a day, which, although a small percentage of the capacity of the plant, indicates the gradual trend toward normal conditions. The Liberty Motor Car Co., Detroit, has asked for immediate shipments and has released a very substantial schedule for the next ninety days. In addition there have been numerous small requisitions which will go to make up a decided improvement in the total output.

H. W. Schnetzky, president, and A. F. Milbrath, secretary and chief engineer of the company, have returned from an extensive trip through the west, surveying business conditions in general and calling on Wisconsin distributors. They report the business outlook favorable. The Earl P. Cooper Co. at Los Angeles, and the Chandler-Hudson Co. at Seattle, are optimistic over conditions and state that the west coast is fast recovering from the business depression.

OHIO SENSES TRUCK DEMAND

COLUMBUS, March 11—Prospects for an active demand for motor trucks within a short time are unusually bright in Columbus and central Ohio territory, according to leading agencies. During the past few months it has been rather quiet and a canvass of the situation shows that many truck users will soon come into the market for replacement of their truck equipment. It has been the custom during the past six months for the truck owners and users to make all repairs on their present equipment to keep them going. Now the time has arrived when their old equipment is in many cases just about worn out and they will be forced into the market.

Tractor Business Improves in South

Dealers Look to Normal Times for Restoration of Former Sales Volume

ATLANTA, March 14—Though it is the opinion among tractor distributers of the Atlanta territory that the crisis in this section has been passed so far as the tractor industry is concerned and that sales are experiencing a gradual improvement, the total volume of business is below the normal mark, and that condition appears likely to exist until the readjustment period has become a thing of the past.

One of the reasons distributers in this section are finding tractor sales rather few and far between is that many of the dealers, especially those in the smaller towns, have strained their credit almost to the breaking point. Fred Cameron, of the John Deere Plow Co.'s Atlanta branch, in a recent trip through south Georgia and the Carolinas, found that many of the smaller dealers were in severe straits. They were unable to make substantial payments on their accounts because they have not been selling enough tractors the past few months to even take care of incidental expenses.

Because of the declines in the prices of their products the farmers haven't the money with which to buy tractors now, and they are unable to obtain additional credit from their bankers in most cases because they are already under heavy obligations. This is the unfavorable condition against which the dealers are working in their efforts to sell tractors. Until that condition experiences material improvement the industry cannot get back to normal.

Cameron told of one dealer who started business a little over a year ago with $2,500 capital, and who now owes $37,500, with only $15,000 worth of notes to take care of it. While that dealer's condition is not typical, there are many experiencing troubles of a kindred nature.

In January the tractor business in the Southeast was really at a standstill, but during February a few sales were made. March has been about on a par with February, but a gradual increase in business is noted and there is a better feeling than for several months. During April and May they are anticipating a much larger volume.

WHARTON TO MAKE FULL LINE

DALLAS, TEXAS, March 12—The manufacture of a very extensive line of automotive apparatus is contemplated by the recently organized Wharton Motors Co., Inc. The line comprises three passenger car models, a four, a six and an eight, two trucks, one of 1 to 1½ tons capacity and the other of 2 to 2½ tons, and a combined tractor and cultivator. The four-cylinder model has a 3½ x 5 in. engine, the six-cylinder model a 3⅛x4½.

Car Design Lowers Rates on Insurance

Standard Frame Marking Secures 20 Per Cent Allowance—Locks Reduce Risks

NEW YORK, March 14—The insurance committee of the N. A. C. C. of which W. E. Metzger is chairman, has sent a bulletin to its members pointing out that insurance costs to the public are influenced by car design and urging members to study the schedule of fire hazards. The bulletin says:

"A very substantial item of expense in connection with ownership and operation of an automobile is insurance. The effect of the new plan of grouping cars by name instead of by list price is becoming better known and appreciated by buyers, and our Directors and Insurance Committee strongly urge that members carefully note the construction features which Underwriters consider as bearing directly on the risk attached to the various forms of insurance, not only for the purpose of having each car grouped as favorably as possible but because makers should aim to keep insurance costs to the public as low as possible.

"These features are listed in the schedule of hazards. The Underwriters believe that by means of theft retardents and positive identification marks, manufacturers can assist in reducing insurance losses. For standard marking of frame they offer 7½ per cent, for standard marking of engine block, 7½ per cent, and an additional 5 per cent for both, making 20 per cent when both frame and engine block are so marked.

"Deductions ranging from 12½ per cent to 20 per cent are allowed for built-in, or integral, approved locking devices; the transmission type secures the greatest reduction. It will be noted that the Manual grants an allowance of 20 per cent from theft rate on Paige-Detroit cars. This is because of their built-in transmission lock. In most cities and territories a 15 per cent reduction is made in theft insurance when the car owner buys a lock of an approved type and attaches it to his car; in many cities, if a car is not equipped with an approved lock a flat extra charge of $15 is made in the theft rate.

"Fire risk is influenced by location of gasoline tanks, their construction, the soundness of the feed system, proximity of carbureter to sparks, the tension and insulation of wiring, exposure of exhaust to drippings and general workmanship and stability."

STOCKHOLDERS RAISE $25,000

AKRON, March 12—Stockholders of the defunct Interlocking Cord Tire Co. of Akron and Mogadore, now in the hands of Elihu Harpham as receiver, and whose four former main officers are under criminal indictment for alleged violation of the Ohio Blue Sky Law, have raised $25,000 in an effort to reorganize and re-establish the company, it is announced by a special stockholders' committee. The committee also announces appointment of Edward R. Kohl as temporary president of the company, succeeding Walter Kline, who resigned following his indictment by the Summit County Grand Jury. R. E. Cartlidge, Akron industrial engineer, has been named treasurer of the new management of the company and C. A. Rukamp has been named secretary. The stockholders will elect a permanent president soon, it is announced.

U. S. C. C. Favors Revision in Contract Obligations

WASHINGTON, March 10—Six months' study of cancellations in representative industries convinced the fabricated production department of the Chamber of Commerce of the United States that this general repudiation of business agreements was largely responsible for the economic disturbances. The National Chamber has recommended that the business interests of the country take steps to prevent the spread of cancellation evil and insure confidence in the written and oral contractual relations.

The Chamber favors revisions in contracts which make the obligations of both seller and buyer equitable with provisions for arbitration; diligent inquiry into credit standing of applicants, report cases where parties cancelled their contracts and establish a "Golden Rule" policy in business. The Chamber recommended that merchants use the services of trade organizations in combating cancellations.

Germany to Open Gates to Light Tractor Test

DETROIT, March 14—Officials of the Ford Motor Co. are much gratified at the report from Berlin that the Reichstag committee on national economics has voted to recommend that the government permit the entry of four light weight American tractor plows for demonstration purposes. This action was taken in the face of strong opposition by German manufacturers.

It is the assumption here that the tractors in question are Fordsons. Negotiations for their entry into Germany have been pending since the visit here of B. F. Graetz several months ago. He expressed confidence that he would be able to get across the border several tractors which were furnished him. If the Reichstag adopts the recommendation of its committee it is believed it will presage the opening of an enormous new market for tractors.

POLICE GUARD TURIN PLANTS

NEW YORK, March 15—A dispatch from Turin, Italy, says the police have been stationed in the Michelin factories where the workers have been locked out. This action was taken because of acts of violence committed by the workers.

Insurance Companies Drop Full Coverage

Aetna to Make Insured Bear Initial Losses in Collisions—Urge Co-operation

NEW YORK, March 14—An important step toward reducing the number of automobile accidents and toward lessening insurance collision rates has been taken by the Aetna Life Insurance Co. and its affiliated companies, the Aetna Casualty & Surety Co. and the Automobile Insurance Co. of Hartford, in eliminating the sale of full coverage collision insurance from March 9 on. Under the new plan only that form of collision insurance which provides for the insured paying the first $50 or $100 of each collision loss will be sold.

This action has been taken individually by the companies and is designed to throw the burden of careless and negligent motor car operation upon the operator. Insurance brokers and agents have been notified of the company's action and the reasons for it. Their support has been particularly sought in a movement to eliminate full collision coverage insurance in the Greater New York zone because of the heavy traffic.

By making this change company officials expect to accomplish something more effective and constructive in the way of reducing preventable insurance accidents than the mere action of increasing rates. Decreased losses will be reflected in decreased rates, so that the main benefit will be to the public.

As part of the Aetna's present move to reduce preventable losses, the company is also advocating the equipping of cars with approved types of locks to lessen the danger of theft.

Safety Precautions to Win Lower Rates

MILWAUKEE, March 12—Wisconsin pioneered in workmen's compensation insurance covering accidents or fatalities, and since that time every manufacturer, or dealer, in any kind of industry or trade has paid the same premium rate for this state-enforced insurance as every other employer in his line.

Through the efforts of employers, including some of the automobile manufacturers, makers of parts and equipment and service plant owners, the Wisconsin law is now to be amended to give the employer who promotes safety in his establishment a lower premium rate and expense than the one who gives little or no attention to these items, regardless of class of enterprise.

The bill will be passed by the Wisconsin legislature, at least in its chief essential, and it is predicted that the move here will be followed by the other states having similar state-enforced insurance.

The new statute provides for individual experience rating, per establishment.

Industry Shows Gain While Others Slump

Cleveland Survey Shows Falling Employment in Other Lines —Look for Fair Year

CLEVELAND, March 15—The automobile industry is moving back toward normal conditions much more rapidly than are other lines of industry in this city, according to a survey made by the Industrial Relations Committee of the Cleveland Chamber of Commerce. The survey was made for the United States Department of Labor and the results were sent to Washington. Each month a similar survey will be made and the figures given to Washington, so that the labor department may keep an accurate line on developments here.

The report disclosed that there was an increase of 10 per cent in the number of employees in 18 plants engaged in making products for the automobile industry. In these 18 plants, 5542 men were employed on Jan. 31, while on the last day in February the number had increased to 6120. The plants in this group of 18 include all of the automobile making concerns in the city with the exception of one, as well as most of the factories in which automobile parts are made.

While the automotive industry was making this 10 per cent headway, other lines in the survey were going back 1.9 per cent from an employment standpoint. The committee sent out questionnaires to approximately 100 factories and 97 responded. In these 97 factories there were 58,116 men employed on the last day of January, while on Feb. 28, the number had decreased to 57,001. That is a loss of 1.9 per cent in the number of employees.

Here is what the survey disclosed:

Group—	No. of Employees Jan. 31	Feb. 28
Food	3,071	2,702
Textiles	5,928	6,045
Iron and steel	21,081	20,488
Lumber	1,119	1,163
Paper	1,170	1,100
Chemicals	3,242	3,141
Metal	869	747
Miscellaneous	16,088	15,495

At the automobile plants that were questioned it was brought out that orders were in February more than 10 per cent greater than they were in January, and this brought the prediction that more men would be employed in the present month. March has started off well.

Sixty per cent of the normal production or employment capacity of the 97 factories that responded in the survey is being used to-day, according to an estimate made at offices of the industrial relations committee. It is estimated that in normal times, the factories that were employing 57,001 persons on Feb. 28 would have on their payrolls approximately 100,000.

Predictions have been made that production for the year would be about 60 per cent of what it was in the boom days of the war.

Parts Makers to Push Service Station Plan

NEW YORK, March 16.—Representatives of some of the largest parts manufacturers in the country will meet here late this week for further discussion of the plan which has been in process of development for some time, for the establishment of major service stations and branches in all parts of the country. Better and more economical service for motor car owners by making constantly available to them complete stocks of major parts is the chief purpose of the plan. It is the purpose to carry at these stations the principal parts used in most of the assembled cars.

Many parts manufacturers are coming to the conclusion that if their products are to be properly serviced some such plan is necessary. It is not the purpose to come into competition with the dealer and garage men but rather to co-operate with them, except in the case of orphan cars and trucks. Supplies at these stations would be much more complete than any individual dealer could afford to handle.

Harvester and Case Lower Tractor Prices

CHICAGO, March 17—In anticipation of lower production costs, the International Harvester Co. has made the following reduction in tractor prices: Titan 10-20, reduced $200; International 8-16, reduced $150; International 15-30, reduced $350.

In addition, reductions ranging from 10 to 15 per cent of the wholesale price have been made on about one-third of the line of implements and machinery manufactured by this company.

A reduction of 15 per cent has been made by the J. I. Case Plow Works. This cut applies to all the products of this company, including tractors and other power farming machinery.

DORRIS PLANS EXPANSION

ST. LOUIS, March 16—At a special meeting called for March 21, stockholders of the Dorris Motor Car Co. will consider the proposition of forming a holding company to purchase all the property and improvements owned by the company, in this way permitting further manufacturing expansion by turning the fixed assets of the company into liquid assets. The company, according to its secretary, J. F. Culver, has been unable to expand and increase its output of cars to supply the demand on account of the lack of liquid capital. The holding company will be capitalized for at least $250,000.

Goodyear Meeting Is Again Deferred

Stockholder Ratification of Financing Plan Held Over to March 22

AKRON, March 15—The meeting of stockholders of the Goodyear Tire & Rubber Co. adjourned to to-day from March 4, for the purpose of finally ratifying the company's refinancing program which involves a loan of $85,000,000, was again adjourned to March 22 to-day upon request of special committees negotiating with creditors of the company. Announcement of the continued adjournment of the meeting came as a surprise to stockholders, as it had been announced officially by the company that stockholders proxies received showed more than a 75 per cent majority vote in favor of the refinancing and reorganization plans.

The eleventh hour hitch in proceedings leading to definite consummation of the refinancing program is said to have been with merchandise creditors. The special merchandise creditors committee has gained the assent of more than 80 per cent of merchandise creditors to the "plan of readjustment" included in the financing negotiations, but it is stated that practically unanimous assent of creditors is desired and is necessary. Creditors refusing to yield are holding out, it is said, in the hope that their claims will be settled either by Goodyear or by friendly interests.

Stadleman announced that progress was being made in winning over the merchandise creditors holding out, and that with continued gain of ground he expected that the stockholders meeting could be called soon.

Fisk Resumes Schedule at Reduced Wage Rate

CHICOPEE, MASS., March 14—The Fisk Rubber Co., which has been operating on a three-day schedule since Dec. 1, to-day resumed full time and a wage reduction on both day and piece work was put into effect, which amounts to an average of 10 per cent. About 1600 employees are affected. Increased overhead expenses under the shortened schedule makes the return to full time and wage reduction necessary, the company states.

RECEIVER NAMED FOR SUPREME

AKRON, March 12—Scott Kenfield, former Akron city solicitor, has been named receiver of the Supreme Cord Tire & Rubber Co. of Akron, on petition of Julia Nunamaker and A. C. Bender, representing the estate of Jefferson Nunamaker. The charge is made by the petitioning stockholders that the company's former fiscal agent absconded with $10,000 paid by the Nunamaker estate for 100 shares of stock, which, it is claimed, were never delivered. It is also charged that the firm is insolvent.

Studebaker Demand in Excess of 1920

Erskine Looks for New Production Mark—Earnings of $9,822,854 Reported

SOUTH BEND, IND., March 16—"If general conditions become no worse than they are now our business should almost certainly exceed that of last year," was the assertion made by A. R. Erskine, president of the Studebaker Corp. in presenting the annual report to the stockholders to-day. The report shows net profits of $9,822,054 after deductions of Federal taxes, depreciation and other fixed charges. This was equivalent to $15.18 a share on the $60,000,000 of common stock compared with $20.69 a share on the $45,000,000 of common stock outstanding at the close of 1919. Gross sales for 1920 exceeded any other year in the history of the company, having been $90,652,362, compared with $66,383,307 of 1919.

The income accounts for 1920 and 1919 follow:

	1920	1919
Net sales	$90,652,362	$66,383,307
Manuf. cost, depr., etc.	78,521,555	55,099,844
Operating profit	$12,130,807	$11,283,463
Other income	120,014	......
Total income	$12,250,821	$11,283,463
Interest, etc.	......	116,951
Federal taxes	2,428,767	1,854,229
Net profits	$9,822,054	$9,312,283
Preferred dividends	710,150	748,475
Common dividends	3,937,500	2,100,000
Surplus	$5,174,404	$6,463,808
Profit and loss surp.	*$13,467,047	$20,925,583

*After deduction of $15,000,000 stock dividend. $872,940 net losses actually sustained in 1920 or anticipated in completing final liquidation of wagon business, etc.

In his statement concerning the outlook for 1921, President Erskine said:

"The demand for Studebaker cars is quite heavy from all sections of the country, except in a few spots, and in a number of places is double and treble what it was last spring. March sales will probably exceed 5000 cars. Manufacturing schedules call for 5235 cars in March, 5440 in April, 7015 in May, and 7320 in June, with production proceeding nicely and under economic conditions."

Develop Scoutomobile Weighing 150 Pounds

BOSTON, March 14—A striking curiosity, a two passenger automobile said to weigh less than 150 lbs., has been developed by C. H. Martin of the Martin Rocking Fifth Wheel Co. in conjunction with C. R. Gurney, consulting engineer. The machine is claimed to have a maximum speed of 30 m.p.h. and to travel 75 miles on a gallon of gasoline. It seats two people side by side and can be completely housed in for protection in bad weather. There is a single front steering wheel which tracks with one of the rear wheels.

The car is made largely of aluminum-alloy and magnesium metal; it has a 5 h.p. opposed motor and sliding gear transmission, but no universal joints or differential. The wheel arrangement and spring suspension are said to be such that it will ride comfortably. One of the advantages claimed is that the car can be pushed through an ordinary doorway and stored in the front hall or office.

Martin says: "The machine will not be ready for the market for some time, but we are inviting criticism and suggestions from dealers and users. Before offering it to the public we propose subjecting it to months of tests. The selling price has not yet been fixed, but in view of the high priced light alloys extensively used in its construction it probably will be the highest priced automobile for its weight in the country."

Ford Is Operating on Own Resources

be possible, though there may be some banks unable to continue the loan and there may be others, which for various reasons, will refuse this sixth renewal. The personal taxes of Henry and Edsel Ford are declared to be negligible when taken in comparison with the other indebtedness.
